<p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>
---	---

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 1
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing</u></p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <p>(a) the step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p>

<p><u>screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 20px;">wherein said method delivers said video graphic presentation.</p>	<p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 1
175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to	1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including: (a) the step of receiving at said remote site a

<p>detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>
--	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 1
-----------------------	----------------------------------

<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>1. A method of processing control signals and controlling equipment at a remote site based on broadcast transmissions including:</p> <p>(a) the step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and</p> <p>(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.</p>
---	---

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 1
179. A method of outputting a video graphic presentation at a receiver station including:	1. A method of processing control signals and controlling equipment at a remote site based on

receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;
passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;
displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;
detecting said at least a first discrete signal;
passing said at least a first discrete signal to at least one processor;
organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;
responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;
passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and
displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,
wherein said method delivers said video graphic presentation.

broadcast transmissions including:
(a) the step of receiving at said remote site a broadcast carrier transmission;
(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;
(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;
(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;
(e) the step of said computer control means determining based on instructions included in said control signals whether receiver means at said remote site is operating; and
(f) the step of directing, based on the result of said determination step, said information transmission and a selected portion of said control signals to (1) said receiver means and associated computer equipment or (2) a recorder means activated by said computer control means.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 2
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) the step of receiving at a remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of control signals to a computer control means at said remote site;</p> <p>(e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and</p> <p>(f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 2
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) the step of receiving at a remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of control signals to a computer control means at said remote site;</p> <p>(e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and</p> <p>(f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>

<p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 2
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) the step of receiving at a remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of control signals to a computer control means at said remote site;</p> <p>(e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and</p> <p>(f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 2
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <ul style="list-style-type: none"> (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code inputted into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 2
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at 	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <ul style="list-style-type: none"> (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier

<p>said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>
---	--

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 2
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target</u></p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including: (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the</p>

<p>processor to process data; transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>comparison step provides a match between the inputted code and the selected portion of the control signals.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 2
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time;</p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including: (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code inputted into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>

<p>and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 2
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of</u></p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including: (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code inputted into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>

<p><u>receiver stations; and</u> transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 2
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including: (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 2
<p>143. A method of outputting a video presentation</p>	<p>2. A method of processing control signals and</p>

<p>at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>controlling equipment at a remote site based on a broadcast transmission, including:</p> <ul style="list-style-type: none"> (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.
---	---

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 2
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said 	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <ul style="list-style-type: none"> (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.

<p>downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 2
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) the step of receiving at a remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of control signals to a computer control means at said remote site;</p> <p>(e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and</p> <p>(f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 2
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 2
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to</p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said</p>

<p>a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and (f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>
--	--

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 2
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed</u></p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including: (a) the step of receiving at a remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said information transmission; (d) the step of passing at least a portion of control signals to a computer control means at said remote site; (e) the step of comparing a selected position of said control signals with a code imputed into said</p>

<p><u>full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 20px;">wherein said method delivers said video graphic presentation.</p>	<p>computer control means on the basis of information contained in said information transmission; and</p> <p>(f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>
--	---

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 2
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor,</u></p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p style="padding-left: 20px;">(a) the step of receiving at a remote site a broadcast carrier transmission;</p> <p style="padding-left: 20px;">(b) the step of demodulating said broadcast carrier</p>

<p>said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of control signals to a computer control means at said remote site;</p> <p>(e) the step of comparing a selected position of said control signals with a code inputted into said computer control means on the basis of information contained in said information transmission; and</p> <p>(f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>
--	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 2
177. <u>A method of delivering a video graphic presentation at at least one receiver station of a</u>	2. A method of processing control signals and controlling equipment at a remote site based on a

<p>plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>broadcast transmission, including:</p> <p>(a) the step of receiving at a remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;</p> <p>(d) the step of passing at least a portion of control signals to a computer control means at said remote site;</p> <p>(e) the step of comparing a selected position of said control signals with a code imputed into said computer control means on the basis of information contained in said information transmission; and</p> <p>(f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.</p>
---	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 2
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal</p>	<p>2. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) the step of receiving at a remote site a broadcast</p>

and a series of video images that each contain at least one graphic image;
passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;
displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;
detecting said at least a first discrete signal;
passing said at least a first discrete signal to at least one processor;
organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;
responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;
passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and
displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,
wherein said method delivers said video graphic presentation.

carrier transmission;

(b) the step of demodulating said broadcast carrier transmission to detect an information transmission therein;

(c) the step of detecting and identifying at said remote site control signals associated with said information transmission;

(d) the step of passing at least a portion of control signals to a computer control means at said remote site;

(e) the step of comparing a selected position of said control signals with a code inputted into said computer control means on the basis of information contained in said information transmission; and

(f) the step of activating a printing means when the comparison step provides a match between the inputted code and the selected portion of the control signals.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 3
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 3
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and</u></p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a</p>

<p>output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and (g) the step of decrypting said information transmission.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 3
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including: (a) a step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients; (f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and (g) the step of decrypting said information transmission.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 3
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <ul style="list-style-type: none"> (a) a step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients; (f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and (g) the step of decrypting said information transmission.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 3
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <ul style="list-style-type: none"> (a) a step of receiving at said remote site a broadcast carrier transmission;

<p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>
--	---

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 3
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least</u></p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list</p>

<p>one of said plurality of receiver stations a target processor to process data; transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>of authorized information recipients; (f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and (g) the step of decrypting said information transmission.</p>
---	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 3
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including: (a) a step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients; (f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and (g) the step of decrypting said information transmission.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 3
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote</u> <u>transmitter station and a second remote transmitter</u> <u>station at least one instruct signal which is effective at</u> <u>a particular receiver station of said plurality of receiver</u> <u>stations to generate locally and output said second</u> <u>image of said video presentation for delivery in</u> <u>conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least</u> <u>one control signal at said at least one of said first</u> <u>remote transmitter station and said second remote</u> <u>transmitter station, said at least one first discrete signal</u> <u>including only partial information of said one of a</u> <u>code and an identifier and said at least one control</u> <u>signal operative to provide said one of a code and an</u> <u>identifier and designate at said at least one of said</u> <u>plurality of receiver stations by organizing said partial</u> <u>information with information contained in a second</u> <u>discrete signal at said at least one of said plurality of</u> <u>receiver stations, wherein said one of a code and an</u> <u>identifier designates said one of said second image</u> <u>and said device at said particular receiver station and</u> <u>is operative to cause said at least one instruct signal to</u></p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>

<p><u>be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 3
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 3
-----------------------	----------------------------------

<p>143. A method of outputting a video presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <ul style="list-style-type: none"> (a) a step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients; (f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and (g) the step of decrypting said information transmission.
--	---

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 3
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; receiving said one or more control signals at said one of said first remote transmitter station and a 	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <ul style="list-style-type: none"> (a) a step of receiving at said remote site a broadcast carrier transmission; (b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein; (c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission; (d) the step of passing at least a portion of said control signals to a computer control means at said remote site; (e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients; (f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said

<p>second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 3
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 3
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 3
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>
--	---

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 3
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen</u></p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p>

<p><u>video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 20px;">wherein said method delivers said video graphic presentation.</p>	<p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 3
175. <u>A method of delivering a video graphic</u>	3. A method of processing control signals and

presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:

receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;

delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;

receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and

transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,

wherein said method delivers said video graphic presentation.

controlling equipment at a remote site based on a broadcast transmission, including:

(a) a step of receiving at said remote site a broadcast carrier transmission;

(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;

(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;

(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;

(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;

(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and

(g) the step of decrypting said information transmission.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter

station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 3
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 3
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image;</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>3. A method of processing control signals and controlling equipment at a remote site based on a broadcast transmission, including:</p> <p>(a) a step of receiving at said remote site a broadcast carrier transmission;</p> <p>(b) the step of demodulating said broadcast carrier transmission to detect an encrypted information transmission therein;</p> <p>(c) the step of detecting and identifying at said remote site control signals associated with said encrypted information transmission;</p> <p>(d) the step of passing at least a portion of said control signals to a computer control means at said remote site;</p> <p>(e) the step of said computer means identifying the remote site receiver, determining an identification code for said remote site receiver and comparing said identification code for said remote site receiver to a list of authorized information recipients;</p> <p>(f) the step of said computer means directing a selected portion of said control signals to a decryptor means based on a favorable result of said identification step; and</p> <p>(g) the step of decrypting said information transmission.</p>

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 4
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 4
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 4
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 4
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>4. A data receiver system comprising:</p> <p>a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector;</p> <p>a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and</p> <p>a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 4
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>4. A data receiver system comprising:</p> <p>a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector;</p> <p>a controller operatively connected to said switch for causing said switch to select either said first input or</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 4
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 4
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 4
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>4. A data receiver system comprising:</p> <p style="padding-left: 20px;">a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector;</p> <p style="padding-left: 20px;">a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and</p> <p style="padding-left: 20px;">a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 4
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p><u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u></p> <p><u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u></p> <p><u>passing said detected at least a first discrete signal to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>4. A data receiver system comprising:</p> <p>a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector;</p> <p>a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and</p> <p>a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 4
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 4
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

instructions to a transmitter:

receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 4
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p><u>and</u></p> <p><u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>4. A data receiver system comprising:</p> <p>a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector;</p> <p>a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and</p> <p>a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 4
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 4
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 4
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

causing said switch to select either said first input or said second input; and

a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 4
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>4. A data receiver system comprising:</p> <p>a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector;</p> <p>a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and</p> <p>a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 4
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>4. A data receiver system comprising:</p> <p>a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector;</p> <p>a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and</p> <p>a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 4
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>4. A data receiver system comprising: a switch operatively connected to a first input of a broadcast transmission and a second input of a cablecast transmission for selecting either said first input or said second input and transferring the selected transmission to a digital detector; a controller operatively connected to said switch for causing said switch to select either said first input or said second input; and a digital detector operatively connected to said switch for detecting digital data in said selected transmission and for relaying said data to a data processor.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 5
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>5. A television receiver system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals; a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video; a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals; a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal; a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions; said controller programmed with: (1) information as to changing locations or changing timing patterns of said predetermined signals; and (2) information as to composition of said predetermined signals.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 5
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a</u></p>	<p>5. A television receiver system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals; a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals</p>

<p><u>second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image,</u> said method comprising the steps of:</p> <p>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>
--	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 5
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal,</u> said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of</u></p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to</p>

<p><u>generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>
--	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 5
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving video at a transmitter station;</p> <p style="padding-left: 20px;">delivering said video to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image</u></p>	<p>5. A television receiver system comprising:</p> <p style="padding-left: 20px;">a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p style="padding-left: 20px;">a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p style="padding-left: 20px;">a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p style="padding-left: 20px;">a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p style="padding-left: 20px;">a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing</p>

<p><u>for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>said information to a processor; and a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions; said controller programmed with: (1) information as to changing locations or changing timing patterns of said predetermined signals; and (2) information as to composition of said predetermined signals.</p>
--	--

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 5
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of: receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u></p>	<p>5. A television receiver system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals; a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video; a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals; a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal; a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions; said controller programmed with: (1) information as to changing locations or changing</p>

<u>video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u>	timing patterns of said predetermined signals; and (2) information as to composition of said predetermined signals.
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 5
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 5
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 5
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect</u></p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p>

<p>the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>
--	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 5
142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:	5. A television receiver system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions

<p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>
---	---

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 5
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at</u></p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the</p>

<p><u>least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information</u>, based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>audio signal containing embedded signals; a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal; a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions; said controller programmed with: (1) information as to changing locations or changing timing patterns of said predetermined signals; and (2) information as to composition of said predetermined signals.</p>
--	--

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 5
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; <u>receiving said one or more control signals at said</u></p>	<p>5. A television receiver system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals; a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video; a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals; a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal; a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said</p>

<p><u>one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 5
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals</p>

	<p>passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>
--	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 5
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving a video image at a transmitter station;</p> <p style="padding-left: 40px;">delivering said video image to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>5. A television receiver system comprising:</p> <p style="padding-left: 40px;">a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p style="padding-left: 40px;">a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p style="padding-left: 40px;">a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p style="padding-left: 40px;">a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p style="padding-left: 40px;">a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p style="padding-left: 40px;">a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p style="padding-left: 40px;">said controller programmed with:</p> <p style="padding-left: 80px;">(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p style="padding-left: 80px;">(2) information as to composition of said predetermined signals.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 5
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 5
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first</u></p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing timing patterns of said predetermined signals; and</p> <p>(2) information as to composition of said predetermined signals.</p>

<p><u>completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 5
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u> receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor; <u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter</p>	<p>5. A television receiver system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals; a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video; a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals; a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal; a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions; said controller programmed with: (1) information as to changing locations or changing timing patterns of said predetermined signals; and (2) information as to composition of said predetermined signals.</p>

<p>station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 5
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic</u></p>	<p>5. A television receiver system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals;</p> <p>a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video;</p> <p>a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals;</p> <p>a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and</p> <p>a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions;</p> <p>said controller programmed with:</p> <p>(1) information as to changing locations or changing</p>

<p><u>image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.</p>	<p>timing patterns of said predetermined signals; and (2) information as to composition of said predetermined signals.</p>
---	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 5
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said</u></p>	<p>5. A television receiver system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video signal containing embedded signals; a first digital detector operatively connected to said line receiver for receiving the selected portions of video lines containing the video embedded signals and detecting the presence of a first predetermined signal in said selected lines of video; a filter for receiving an audio signal of said analog television transmission and selecting portions of the audio signal containing embedded signals; a second digital detector operatively connected to said filter for receiving the selected portions of the audio signal containing the audio embedded signals and detecting the presence of a second predetermined signal in said selected portions of said audio signal; a storage device operatively connected to said first and said second digital detectors for receiving and storing information contained in at least one of said first and second predetermined signals, and passing said information to a processor; and a controller operatively connected to said detectors, said line receiver and said filter for controlling the selected portions of said video and audio signals passed from said line receiver and filter, respectively, to said detectors based on either a location or a timing pattern of the selected portions; said controller programmed with: (1) information as to changing locations or changing timing patterns of said predetermined signals; and (2) information as to composition of said predetermined signals.</p>

<u>second completed full-screen video graphic image</u> <u>and only a portion of said first completed full-screen</u> <u>video graphic image,</u> wherein said method delivers said video graphic presentation.	
---	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 6
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and</p> <p>a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 6
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and</p> <p>a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 6
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 6
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 6
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving said transmission and

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 6
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 6
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 6
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and</p> <p>a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 6
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p style="padding-left: 20px;">a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and</p> <p style="padding-left: 20px;">a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 6
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 6
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</u> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 6
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of: receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 6
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 6
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and</p> <p>a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 6
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and

a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 6
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and</p> <p>a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 6
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and</p> <p>a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 6
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>6. A system for identifying a predetermined signal in a television program transmission in which a plurality of signal types are transmitted said signal being transmitted in a varying location or a varying timing pattern, said television program transmission being separately defined from standard analog video and audio television, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving said transmission and detecting said predetermined signal in said transmission based on either a specific location or a specific time; and a controller operatively connected to said detector for causing said detector to detect said predetermined signal based on either a specific location or time, said controller being programmed with either the varying locations or the varying timing pattern of said signal.

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 7
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 7
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at</u></p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble</p>

<p><u>least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 7
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 7
<p>84. <u>A method of delivering a video presentation</u> at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and <u>said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time; a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 7
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at 	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system</p>

<p>said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 7
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, <u>said at least one processor instruction is effective at said at least one of</u></p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p>

<p><u>said plurality of receiver stations to generate and output only a portion of said video presentation</u>, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 7
<p>116. <u>A method of delivering a video presentation</u> at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station</u> and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>

<p><u>transferring said at least one control signal to said at least one origination transmitter before a specific time;</u> and <u>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</u></p>	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 7
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and</p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time; a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>

<p>is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 7
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 7
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time; a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 7
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter 	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time; a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and a controller operatively connected to said detector

<p>station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor instructions to a transmitter; receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>
--	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 7
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of: receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising: a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time; a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or</p>

and transmitting said one or more control signals from said origination transmitter before a specific time.	with either the varying location or the varying timing pattern of said signal.
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 7
<p>162. <u>A method of delivering a video presentation</u> at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving a video image at a transmitter station; delivering said video image to a transmitter; receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and <u>wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station. 	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time; a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 7
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that</p>

<p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; -</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 7
171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at	7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said

least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

transmission being separately defined from standard analog video and audio television, said system comprising:

a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;

a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and

a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 7
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter</p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>

<p>before a specific time, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 7
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <p>a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and</p> <p>a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 7
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal; responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>7. A system for locating or identifying a specific signal in a television program transmission that contains digital information and for assembling information contained in said specific signal, said transmission being separately defined from standard analog video and audio television, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least some information of said transmission and detecting said specific signal at a specific location or time; a storage device operatively connected to said digital detector for receiving detected digital information of said specific signal and assembling at least some of said digital information into either information or instruction message units; and a controller operatively connected to said detector and said storage device for causing said detector to locate, detect or output said signal and for controlling a technique used by said storage device to assemble message units, said controller being programmed with information of the composition of said signal or with either the varying location or the varying timing pattern of said signal.

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 8
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 8
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable</u></p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p>

<p><u>processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 8
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from</p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

said origination transmitter before a specific time.	
--	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 8
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>8. A television receiver system comprising:</p> <ul style="list-style-type: none"> a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals; a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal; a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission; a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 8
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p>	<p>8. A television receiver system comprising:</p> <ul style="list-style-type: none"> a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;

<p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 8
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one</u></p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p>

<p><u>processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 8
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the</p>	<p>8. A television receiver system comprising: a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals; a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal; a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission; a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

<p>communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 8
<p>123. <u>A method of delivering a video presentation</u> at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an</u></p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

<p>identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 8
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 8
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>8. A television receiver system comprising: a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals; a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal; a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission; a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 8
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at</u></p>	<p>8. A television receiver system comprising: a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals; a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal; a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital</p>

<p><u>said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 8
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said</p>

<p>or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 8
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p>transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 8
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and</p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 8
171. <u>A method of delivering a video graphic</u>	8. A television receiver system comprising:

presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;

a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;

a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;

a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and

a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 8
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more</p>	<p>8. A television receiver system comprising:</p> <p>a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p>a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p>a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p>a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p>a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 8
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p style="padding-left: 20px;">delivering said received first completed full-screen video graphic image to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more instruct signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p style="padding-left: 20px;">wherein said method delivers said video graphic</p>	<p>8. A television receiver system comprising:</p> <p style="padding-left: 20px;">a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals;</p> <p style="padding-left: 20px;">a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal;</p> <p style="padding-left: 20px;">a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission;</p> <p style="padding-left: 20px;">a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and</p> <p style="padding-left: 20px;">a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.</p>

presentation.	
---------------	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 8
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>8. A television receiver system comprising:</p> <ul style="list-style-type: none"> a filter for receiving one of either video or audio of an analog television transmission and selecting portions of said analog transmission that contain digital signals; a first digital detector operatively connected to said filter for receiving said selected portions of said analog transmission and detecting a first digital signal; a second digital detector for receiving information of a selected television program transmission that is separately defined from standard analog television, said second digital detector detecting a second digital signal in said separately defined television program transmission; a storage device operatively connected to said first and said second digital detectors for receiving detected digital information and assembling said detected information into message units; and a controller operatively connected to said first detector, said second detector and said storage device, said controller controlling the operation of said first detector and said second detector and controlling the manner by which said storage device assembles message units.

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 10
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>10. A television receiver system comprising:</p> <p>a receiver for receiving a selected portion of a television program transmission that is not a standard television signal;</p> <p>a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units;</p> <p>a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 10
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>10. A television receiver system comprising:</p> <p>a receiver for receiving a selected portion of a television program transmission that is not a standard television signal;</p> <p>a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units;</p> <p>a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 10
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>10. A television receiver system comprising: a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 10
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and <u>said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>10. A television receiver system comprising:</p> <ul style="list-style-type: none"> a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 10
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>10. A television receiver system comprising:</p> <ul style="list-style-type: none"> a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal; passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 10
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, <u>said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>10. A television receiver system comprising: a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message</p>

<p>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data; transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>units.</p>
--	---------------

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 10
<p>116. <u>A method of delivering a video presentation</u> at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of: <u>receiving a first discrete signal at an origination transmitter station</u> and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal; receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; <u>transferring said at least one control signal to said at</u></p>	<p>10. A television receiver system comprising: a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

<u>least one origination transmitter before a specific time;</u> and <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 10
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 20px;">receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</p>	<p>10. A television receiver system comprising:</p> <p style="padding-left: 20px;">a receiver for receiving a selected portion of a television program transmission that is not a standard television signal;</p> <p style="padding-left: 20px;">a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal;</p> <p style="padding-left: 20px;">a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units;</p> <p style="padding-left: 20px;">a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 10
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>10. A television receiver system comprising:</p> <p>a receiver for receiving a selected portion of a television program transmission that is not a standard television signal;</p> <p>a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units;</p> <p>a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 10
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>10. A television receiver system comprising:</p> <ul style="list-style-type: none"> a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 10
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>10. A television receiver system comprising:</p> <ul style="list-style-type: none"> a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.

<p>instructions to a transmitter; receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 10
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>10. A television receiver system comprising: a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 10
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving a video image at a transmitter station; delivering said video image to a transmitter; receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and <u>wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station. 	<p>10. A television receiver system comprising:</p> <ul style="list-style-type: none"> a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 10
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full- 	<p>10. A television receiver system comprising:</p> <ul style="list-style-type: none"> a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</p> <p>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>receiver for receiving said selected portion and detecting a digital signal;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units;</p> <p>a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 10
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>10. A television receiver system comprising:</p> <p>a receiver for receiving a selected portion of a television program transmission that is not a standard television signal;</p> <p>a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal;</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units;

a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 10
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>10. A television receiver system comprising:</p> <p>a receiver for receiving a selected portion of a television program transmission that is not a standard television signal;</p> <p>a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units;</p> <p>a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 10
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>10. A television receiver system comprising:</p> <p>a receiver for receiving a selected portion of a television program transmission that is not a standard television signal;</p> <p>a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal;</p> <p>a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units;</p> <p>a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 10
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal; responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <p>wherein said method delivers said video graphic presentation.</p>	<p>10. A television receiver system comprising:</p> <ul style="list-style-type: none"> a receiver for receiving a selected portion of a television program transmission that is not a standard television signal; a digital detector operatively connected to said receiver for receiving said selected portion and detecting a digital signal; a storage device operatively connected to said digital detector for receiving detected digital information and assembling said detected information into message units; a controller operatively connected to said receiver, said detector and said storage device, said controller controlling said receiver to pass selected information to said detector, said detector to pass detected information to said storage device, and said storage device to assemble detected information into message units.

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 11
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 11
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 11
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 11
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>11. A television receiver system comprising:</p> <ul style="list-style-type: none"> a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 11
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>11. A television receiver system comprising:</p> <ul style="list-style-type: none"> a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern;

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 11
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 11
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 11
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 11
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>11. A television receiver system comprising:</p> <p>a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern;</p> <p>a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 11
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>11. A television receiver system comprising:</p> <ul style="list-style-type: none"> a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 11
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>11. A television receiver system comprising:</p> <ul style="list-style-type: none"> a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 11
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 11
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 11
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p style="padding-left: 40px;">receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>passing, to said video monitor based on said step of responding to at least one processor instruction, <u>only a portion of a second completed full-screen video graphic image;</u> and</p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>signal in said transmission, said first processor being programmed with information of a varying location or timing pattern;</p> <p>a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 11
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>11. A television receiver system comprising:</p> <p>a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

or timing pattern;

a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 11
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>11. A television receiver system comprising:</p> <p>a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern;</p> <p>a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 11
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>11. A television receiver system comprising:</p> <p>a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern;</p> <p>a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 11
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>11. A television receiver system comprising: a first processor for receiving information of a selected television program transmission and detecting a specific signal in said transmission based upon a location or timing pattern of said specific signal in said transmission, said first processor being programmed with information of a varying location or timing pattern; a second processor operatively connected to said first processor for receiving and processing information of said specific signal, and for identifying when and where to pass said information based upon said information, and passing said information.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 12
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 12
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and</u></p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause</p>

<p>output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>said processor to cause said detector to detect different signals.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 12
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 12
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals; a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 12
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; generating an image to replace only a portion of <u>said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals; a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 12
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals; a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and said processor loading said operating instructions</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 12
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals; a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 12
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 12
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 12
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals; a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 12
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of: receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals; a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 12
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals; a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 12
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p><u>receiving a video image at a transmitter station;</u></p> <p><u>delivering said video image to a transmitter;</u></p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p><u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u></p> <p><u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 12
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u></p> <p><u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u></p> <p><u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u></p> <p><u>detecting said at least a first discrete signal of said downloadable code;</u></p> <p><u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p><u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 12
171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is	12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;

a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and

said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 12
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 12
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>12. A reprogrammable system comprising:</p> <p>a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and</p> <p>said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 12
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>12. A reprogrammable system comprising: a digital detector for receiving information of a transmission and detecting digital signals in said transmission, said digital signals including new operating instructions; a processor operatively connected to said digital detector for receiving and processing information of some of said digital signals, said processor identifying those of said operating instructions addressed to said processor, said processor instructing said detector to detect and pass specified signals; a memory device operatively connected to said processor for holding operating instructions addressed to said processor, said operating instructions controlling the operation of said processor; and said processor loading said operating instructions that are addressed to said processor into said memory device to thereby reprogram said processor, said operating instructions including instructions to cause said processor to cause said detector to detect different signals.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

This Page Blank (uspto)

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 13
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 13
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 13
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 13
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>13. A signal processing system comprising:</p> <ul style="list-style-type: none"> a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 13
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>13. A signal processing system comprising:</p> <ul style="list-style-type: none"> a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; generating an image to replace only a portion of <u>said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 13
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 13
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 13
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 13
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>13. A signal processing system comprising:</p> <p>a digital detector for detecting digital signals;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information;</p> <p>a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions that control said processor; and</p> <p>a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 13
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 13
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of: receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

<p>instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 13
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>13. A signal processing system comprising:</p> <p>a digital detector for detecting digital signals;</p> <p>a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information;</p> <p>a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals;</p> <p>a memory device operatively connected to said processor for holding operating instructions that control said processor; and</p> <p>a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 13
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 13
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 13
171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is	13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information;

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals;

a memory device operatively connected to said processor for holding operating instructions that control said processor; and

a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 13
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>13. A signal processing system comprising:</p> <ul style="list-style-type: none"> a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 13
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>13. A signal processing system comprising:</p> <ul style="list-style-type: none"> a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 13
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>13. A signal processing system comprising: a digital detector for detecting digital signals; a processor operatively connected to said digital detector for receiving and processing information of a signal detected by said detector, processing the received detected signals to identify how and where to pass said information; a plurality of apparatus operatively connected to said processor, said processor transferring said detected signals to said apparatus that are addressed by said signals or to be controlled by said signals; a memory device operatively connected to said processor for holding operating instructions that control said processor; and a controller operatively connected to said detector and said memory device for controlling the detector in its detection of signals.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 14
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 14
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image</u></p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p>

<p><u>containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 14
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in</u></p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p>

<p><u>conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 14
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving video at a transmitter station;</p> <p style="padding-left: 20px;">delivering said video to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p style="padding-left: 20px;">transferring said first discrete signal to said transmitter; and</p> <p style="padding-left: 20px;">transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>14. A television receiver station comprising:</p> <p style="padding-left: 20px;">a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p style="padding-left: 20px;">an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p style="padding-left: 20px;">a storage device for receiving and storing television programming;</p> <p style="padding-left: 20px;">means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p style="padding-left: 20px;">a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p style="padding-left: 20px;">a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and</p>

	passing programming to either said output device or to said storage device based upon said scheduled information.
--	---

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 14
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p style="padding-left: 20px;">passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>14. A television receiver station comprising:</p> <p style="padding-left: 20px;">a plurality of receiver/ distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p style="padding-left: 20px;">an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p style="padding-left: 20px;">a storage device for receiving and storing television programming;</p> <p style="padding-left: 20px;">means for selectively receiving television programming from either one of said receiver/ distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p style="padding-left: 20px;">a processor operatively connected to at least one of said plurality of receiver/ distributors for receiving the programming and the programming identification information; and</p> <p style="padding-left: 20px;">a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/ distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 14
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction;</u> and</p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 14
<p>116. <u>A method of delivering a video presentation</u> at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally</u></p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p>

<p><u>generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/ distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/ distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/ distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
--	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 14
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second</u></p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/ distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/ distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of</p>

<p><u>image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations,</u> wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>said plurality of receiver/distributors for receiving the programming and the programming identification information; and a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
--	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 14
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p>	<p>14. A television receiver station comprising: a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming; an output device for displaying television programming or transmitting television programming to a remote subscriber station; a storage device for receiving and storing television programming; means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said</p>

<p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>output device; a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
---	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 14
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>14. A television receiver station comprising: a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming; an output device for displaying television programming or transmitting television programming to a remote subscriber station; a storage device for receiving and storing television programming; means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device; a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and</p>

	passing programming to either said output device or to said storage device based upon said scheduled information.
--	---

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 14
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p style="padding-left: 20px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>14. A television receiver station comprising:</p> <p style="padding-left: 20px;">a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p style="padding-left: 20px;">an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p style="padding-left: 20px;">a storage device for receiving and storing television programming;</p> <p style="padding-left: 20px;">means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p style="padding-left: 20px;">a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p style="padding-left: 20px;">a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 14
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 14
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein</p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television</p>

<p>said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station. 	<p>programming and programming identification signals identifying the programming;</p> <ul style="list-style-type: none"> an output device for displaying television programming or transmitting television programming to a remote subscriber station; a storage device for receiving and storing television programming; means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device; a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.
--	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 14
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said 	<p>14. A television receiver station comprising:</p> <ul style="list-style-type: none"> a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming; an output device for displaying television programming or transmitting television programming to a remote subscriber station; a storage device for receiving and storing television programming; means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said

<p>downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 14
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image,</u></p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of</p>

<p><u>wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
---	---

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 14
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first</p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p>

<p>completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 14
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor</p>	<p>14. A television receiver station comprising: a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals</p>

<p>that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
---	---

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 14
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video</p>	<p>14. A television receiver station comprising:</p> <p>a plurality of receiver/distributors with at least one receiving a television programming transmission, each transmission including the television programming and programming identification signals identifying the programming;</p> <p>an output device for displaying television programming or transmitting television programming</p>

<p>monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and</p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>to a remote subscriber station;</p> <p>a storage device for receiving and storing television programming;</p> <p>means for selectively receiving television programming from either one of said receiver/distributors or said storage device and selectively transferring the received television programming to either said storage device or to said output device;</p> <p>a processor operatively connected to at least one of said plurality of receiver/distributors for receiving the programming and the programming identification information; and</p> <p>a controller operatively connected to said processor for receiving specific unit programming identification information, identifying a specific unit of television programming received at a specific receiver/distributor by comparing of received identification information to previously received scheduled program identification information, and passing programming to either said output device or to said storage device based upon said scheduled information.</p>
--	---

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 15
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 15
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p>

<p><u>second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>inputting at least part of a television programming transmission to said processor; detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>
--	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 15
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the</p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of: inputting to said controller identification information of at least one specified television program unit; inputting at least part of a television programming transmission to said processor; detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p>

communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.	inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.
--	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 15
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit; inputting at least part of a television programming transmission to said processor; detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates

claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 15
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 15
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method</p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively</p>

<p>comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 15
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming</p>

<p><u>information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>
--	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 15
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means</p>

<p><u>including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 15
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 40px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 40px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 40px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 40px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 40px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p style="padding-left: 40px;">inputting to said controller identification information of at least one specified television program unit;</p> <p style="padding-left: 40px;">inputting at least part of a television programming transmission to said processor;</p> <p style="padding-left: 40px;">detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p style="padding-left: 40px;">inputting information of said data to said controller, determining based on said program unit information</p>

<p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>
---	--

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 15
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal; responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of: inputting to said controller identification information of at least one specified television program unit; inputting at least part of a television programming transmission to said processor; detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 15
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively</p>

<p><u>station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 15
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for</p>

<p><u>includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p style="padding-left: 20px;">inputting to said controller identification information of at least one specified television program unit;</p> <p style="padding-left: 20px;">inputting at least part of a television programming transmission to said processor;</p> <p style="padding-left: 20px;">detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p style="padding-left: 20px;">inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 15
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving a video image at a transmitter station;</p> <p style="padding-left: 20px;">delivering said video image to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 20px;">transferring said at least said first of said plurality of</p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p style="padding-left: 20px;">inputting to said controller identification information of at least one specified television program unit;</p> <p style="padding-left: 20px;">inputting at least part of a television programming transmission to said processor;</p> <p style="padding-left: 20px;">detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p style="padding-left: 20px;">inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to</p>

discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.
--	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 15
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

<p><u>image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	
---	--

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 15
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p style="padding-left: 20px;">inputting to said controller identification information of at least one specified television program unit;</p> <p style="padding-left: 20px;">inputting at least part of a television programming transmission to said processor;</p> <p style="padding-left: 20px;">detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p style="padding-left: 20px;">inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

<p><u>conjunction with said only a portion of said first completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 15
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one</p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

<p>or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 15
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television program unit;</p> <p>inputting at least part of a television programming transmission to said processor;</p> <p>detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and</p> <p>inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

<p><u>graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 15
<p>179. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed</u></p>	<p>15. A method for identifying and selecting television programming in a system that is adapted to direct selected television programming to a television programming output or storage, said system including a processor for receiving and processing at least part of the television programming transmission, a means for transferring said programming selectively from a television programming receiver to a television programming output device or storage device, and a controller for receiving information from said processor and for controlling said means for transferring on the basis of at least some of said information, said method comprising the steps of: inputting to said controller identification information of at least one specified television program unit; inputting at least part of a television programming transmission to said processor; detecting, locating or identifying in said part identification data that identified a specific television program unit in said transmission; and inputting information of said data to said controller, determining based on said program unit information that said specific unit is a specific unit and thereby to enable said controller to select at least a portion of said specific television program unit and cause said means for transferring to transfer information of said selected portion to said television programming output device or storage device.</p>

<p><u>second completed full-screen video graphic image</u> <u>filling the entire surface area of said viewing screen</u> <u>and containing said passed only said portion of said</u> <u>second completed full-screen video graphic image</u> <u>and only a portion of said first completed full-screen</u> <u>video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	
--	--

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 16
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor to decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 16
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor to decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p>

<p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 16
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the</p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected; a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions; a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and a controller operatively connected to said line</p>

communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.	receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.
--	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 16
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected; a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions; a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 16
----------------------	-----------------------------------

<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>
---	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 16
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of</p>

<p><u>first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 16
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p>

<p><u>information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 16
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

<p><u>identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 16
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

video presentation containing said generated only said portion of said video image.	
---	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 16
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected; a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions; a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 16
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising: a line receiver for receiving a video signal of an</p>

<p><u>processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 16
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p>

<p><u>includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>
---	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 16
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving a video image at a transmitter station;</p> <p style="padding-left: 20px;">delivering said video image to a transmitter;</p> <p style="padding-left: 20px;"><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 20px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting said video image and said at least said</p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p style="padding-left: 20px;">a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p style="padding-left: 20px;">a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p style="padding-left: 20px;">a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p style="padding-left: 20px;">a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing</p>

first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	pattern of the signals in the transmission.
--	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 16
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 16
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

<p><u>conjunction with said only a portion of said first completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 16
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control</p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor to decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

<p>signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 16
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising:</p> <p>a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected;</p> <p>a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions;</p> <p>a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and</p> <p>a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

<p><u>video graphic image contains at least one graphic image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 16
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen</u></p>	<p>16. A system for locating an embedded instruct-to-decrypt signal out of a plurality of signals embedded in the video of an analog television transmission and enabling a decryptor a decrypt a portion of the television transmission, said system comprising: a line receiver for receiving a video signal of an analog television transmission and selecting portions of one or more lines of said video that contain embedded signals, said line receiver capable of changing the specific portions of said video lines that are selected; a digital detector operatively connected to said line receiver for receiving said selected portions of video lines that contain the embedded signals, detecting the instruct-to-decrypt signal in said selected portions; a decryptor operatively connected to said digital detector for receiving information on the instruct-to-decrypt signal from said detector and decrypting a portion of said transmission in response to receiving said information; and a controller operatively connected to said line receiver for causing said line receiver to change the specific portions of video selected by said line receiver on the basis of a varying location or timing pattern of the signals in the transmission, said controller having access to information on the varying location or timing pattern of the signals in the transmission.</p>

<u>and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.	
---	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 17
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u> <u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u> <u>communicating one of said at least said first request and a second request to a remote data source;</u> <u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u> <u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> <u>and</u> <u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>17. A system for controlling a decryptor, said system comprising: a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 17
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u> <u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>17. A system for controlling a decryptor, said system comprising: a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 17
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>17. A system for controlling a decryptor, said system comprising: a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 17
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>17. A system for controlling a decryptor, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 17
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>17. A system for controlling a decryptor, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 17
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>17. A system for controlling a decryptor, said system comprising: a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 17
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>17. A system for controlling a decryptor, said system comprising: a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 17
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> <u>transferring said at least one instruct signal to at least one transmitter;</u> <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>17. A system for controlling a decryptor, said system comprising: a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 17
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>17. A system for controlling a decryptor, said system comprising:</p> <p>a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals;</p> <p>a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and</p> <p>a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 17
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>17. A system for controlling a decryptor, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 17
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>17. A system for controlling a decryptor, said system comprising:</p> <ul style="list-style-type: none"> a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals; a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.

<p>instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 17
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p style="padding-left: 20px;"><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p style="padding-left: 20px;">receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p style="padding-left: 20px;">transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>17. A system for controlling a decryptor, said system comprising:</p> <p style="padding-left: 20px;">a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals;</p> <p style="padding-left: 20px;">a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and</p> <p style="padding-left: 20px;">a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 17
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving a video image at a transmitter station;</p> <p style="padding-left: 40px;">delivering said video image to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>17. A system for controlling a decryptor, said system comprising:</p> <p style="padding-left: 40px;">a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals;</p> <p style="padding-left: 40px;">a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and</p> <p style="padding-left: 40px;">a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 17
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p style="padding-left: 40px;">receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>17. A system for controlling a decryptor, said system comprising:</p> <p style="padding-left: 40px;">a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and</p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>signals embedded in said transmission, said detector detecting said signals;</p> <p>a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and</p> <p>a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 17
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>17. A system for controlling a decryptor, said system comprising:</p> <p>a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals;</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 17
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>17. A system for controlling a decryptor, said system comprising:</p> <p>a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals;</p> <p>a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and</p> <p>a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 17
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>17. A system for controlling a decryptor, said system comprising:</p> <p>a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals;</p> <p>a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and</p> <p>a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 17
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>17. A system for controlling a decryptor, said system comprising:</p> <p>a digital detector for receiving at least a portion of a television program transmission, said program transmission comprising a program and a plurality of signals embedded in said transmission, said detector detecting said signals;</p> <p>a decryptor operatively connected to said detector for receiving and decrypting said detected signals; and</p> <p>a controller operatively connected to said decryptor for causing said decryptor to alter its decryption pattern or technique.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 18
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>18. A signal processing system comprising:</p> <p>a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor;</p> <p>a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and</p> <p>a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 18
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>18. A signal processing system comprising:</p> <p>a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor;</p> <p>a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and</p> <p>a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 18
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 18
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u> 	<p>18. A signal processing system comprising:</p> <ul style="list-style-type: none"> a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 18
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>18. A signal processing system comprising:</p> <ul style="list-style-type: none"> a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 18
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 18
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 18
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</p>	<p>18. A signal processing system comprising:</p> <p style="padding-left: 20px;">a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor;</p> <p style="padding-left: 20px;">a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and</p> <p style="padding-left: 20px;">a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 18
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>18. A signal processing system comprising:</p> <p>a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor;</p> <p>a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and</p> <p>a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 18
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 18
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of: receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

<p>instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 18
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>18. A signal processing system comprising:</p> <p>a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor;</p> <p>a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and</p> <p>a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 18
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 18
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 18
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 18
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>18. A signal processing system comprising:</p> <p>a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor;</p> <p>a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and</p> <p>a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 18
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>18. A signal processing system comprising:</p> <p>a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor;</p> <p>a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and</p> <p>a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 18
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>18. A signal processing system comprising: a storage device for receiving signals detected in a program transmission and inputting said signals selectively to a decryptor; a decryptor operatively connected to said storage device for receiving, decrypting, and passing signals to a processor; and a controller operatively connected to said storage device and said decryptor for causing said storage device to identify and pass a specific signal to said decryptor and causing said decryptor to decrypt said specific signal.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 19
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>19. A television subscriber station comprising:</p> <p>a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and</p> <p>a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 19
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>19. A television subscriber station comprising:</p> <p>a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and</p> <p>a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 19
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>19. A television subscriber station comprising: a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 19
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>19. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 19
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>19. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 19
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>19. A television subscriber station comprising: a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 19
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>19. A television subscriber station comprising: a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 19
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>19. A television subscriber station comprising: a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 19
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>19. A television subscriber station comprising:</p> <p>a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and</p> <p>a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 19
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>19. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 19
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>19. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 19
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>19. A television subscriber station comprising: a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 19
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>19. A television subscriber station comprising: a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 19
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p style="padding-left: 40px;">receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>19. A television subscriber station comprising: a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 19
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>19. A television subscriber station comprising: a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 19
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>19. A television subscriber station comprising:</p> <p>a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and</p> <p>a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 19
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>19. A television subscriber station comprising:</p> <p>a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and</p> <p>a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 19
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>19. A television subscriber station comprising:</p> <p>a plurality of decryptors, each decryptor capable of decrypting a selected one of a plurality of portions of a television program transmission; and</p> <p>a processor operatively connected to some of said decryptors for identifying and passing to a selected decryptor an instruct-to-decrypt signal that instructs the selected decryptor to decrypt some of the video portion of said transmission, said instruct-to-decrypt signal comprising a code necessary for the decryption of said program transmission.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 20
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>20. A television subscriber station comprising:</p> <p>a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal;</p> <p>a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and</p> <p>a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 20
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>20. A television subscriber station comprising:</p> <p>a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal;</p> <p>a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and</p> <p>a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 20
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>20. A television subscriber station comprising: a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 20
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>20. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 20
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>20. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 20
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>20. A television subscriber station comprising: a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 20
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>20. A television subscriber station comprising: a decryptor for receiving and decrypting part of the video portion of an encrypted television program - transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 20
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>20. A television subscriber station comprising: a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 20
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>20. A television subscriber station comprising:</p> <p>a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal;</p> <p>a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and</p> <p>a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 20
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>20. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 20
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>20. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 20
<p>157. <u>A method of delivering a video presentation at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>20. A television subscriber station comprising: a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 20
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station. 	<p>20. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 20
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full- 	<p>20. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal;

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and</p> <p>a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 20
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>20. A television subscriber station comprising:</p> <p>a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal;</p> <p>a digital detector operatively connected to said decryptor for receiving information of a separately</p>

<p>programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</p> <p>transferring said at least one discrete signal to a transmitter;</p> <p>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and</p> <p>a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 20
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>20. A television subscriber station comprising:</p> <p>a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal;</p> <p>a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and</p> <p>a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 20
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>20. A television subscriber station comprising:</p> <p>a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal;</p> <p>a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and</p> <p>a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 20
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>20. A television subscriber station comprising: a decryptor for receiving and decrypting part of the video portion of an encrypted television program transmission in response to receiving an instruct-to-decrypt signal; a digital detector operatively connected to said decryptor for receiving information of a separately defined television program transmission, detecting the location or presence of an instruct-to-decrypt signal in said transmission, and outputting digital information of said signal to said decryptor; and a controller operatively connected to said detector for controlling the technique by which said detector locates, detects and outputs signals, said controller being programmed with information as to either signal composition or signal timing.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 21
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 21
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of</u></p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion,</p>

<p><u>completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image</u>, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
---	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 21
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal</u>, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video</u>;</p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or</p>

<p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
--	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 21
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving video at a transmitter station;</p> <p style="padding-left: 40px;">delivering said video to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p style="padding-left: 40px;">transferring said first discrete signal to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>21. A television subscriber station comprising:</p> <p style="padding-left: 40px;">a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p style="padding-left: 40px;">a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p style="padding-left: 40px;">a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p style="padding-left: 40px;">a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p style="padding-left: 40px;">a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 21
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 21
110. <u>A method of outputting a video presentation</u>	21. A television subscriber station comprising:

<p>at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 21
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion,</p>

<p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 21
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at</p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with</p>

<p>least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 21
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal</u>; passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized</u></p>	<p>21. A television subscriber station comprising: a tuner for receiving and tuning to a selected one of a plurality of television program transmissions; a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal; a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal; a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being</p>

<u>information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u>	programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.
---	---

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 21
143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.	21. A television subscriber station comprising: a tuner for receiving and tuning to a selected one of a plurality of television program transmissions; a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal; a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal; a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 21
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 21
<p>157. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 21
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said</p>

<p>receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal; a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
--	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 21
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal</u></p>	<p>21. A television subscriber station comprising: a tuner for receiving and tuning to a selected one of a plurality of television program transmissions; a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal; a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal; a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast</p>

<p><u>based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>practices in effect on a selected transmission or frequency; and a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 21
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p>	<p>21. A television subscriber station comprising: a tuner for receiving and tuning to a selected one of a plurality of television program transmissions; a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal; a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal; a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p>

<p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 20px;">transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 20px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 20px;">transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p style="padding-left: 20px;">wherein said method delivers said video graphic presentation.</p>	<p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
---	---

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 21
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p>	<p>21. A television subscriber station comprising:</p> <p style="padding-left: 20px;">a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p style="padding-left: 20px;">a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p style="padding-left: 20px;">a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p style="padding-left: 20px;">a third processor operatively connected to said</p>

<p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
--	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 21
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire</p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission,</p>

<p>surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p> <p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and</p> <p>a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
--	---

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 21
<p>179. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p>	<p>21. A television subscriber station comprising:</p> <p>a tuner for receiving and tuning to a selected one of a plurality of television program transmissions;</p> <p>a first processor operatively connected to said tuner for locating a selected portion of a selected analog television transmission, detecting digital information in said portion, determining the presence of a first instruct-to-decrypt signal;</p> <p>a second processor operatively connected to said tuner for locating a selected portion of a selected separately defined television program transmission, detecting digital information in said separate portion, determining the presence of a second instruct-to-decrypt signal;</p>

<p>detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>a third processor operatively connected to said tuner, said first processor, and said second processor for controlling the manner by which a selected one of said first and second processors locates, detects or passes signals, said third processor being programmed with information as to either the composition or timing of a signal and with information of the standard broadcast or cablecast practices in effect on a selected transmission or frequency; and a decryptor operatively connected to said first processor and said second processor for receiving, decrypting, and outputting information of said selected television program transmission in response to receiving information of said instruct-to-decrypt signals from said first and second processors.</p>
---	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 22
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>22. A television subscriber station comprising:</p> <p>a receiver for receiving a plurality of television program transmissions;</p> <p>a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned;</p> <p>a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and</p> <p>a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 22
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>22. A television subscriber station comprising:</p> <p>a receiver for receiving a plurality of television program transmissions;</p> <p>a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned;</p> <p>a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and</p> <p>a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 22
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 22
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>22. A television subscriber station comprising:</p> <p>a receiver for receiving a plurality of television program transmissions;</p> <p>a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned;</p> <p>a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and</p> <p>a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 22
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>22. A television subscriber station comprising:</p> <p>a receiver for receiving a plurality of television program transmissions;</p> <p>a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned;</p> <p>a decryptor operatively connected to said receiver</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 22
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 22
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 22
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>22. A television subscriber station comprising:</p> <p>a receiver for receiving a plurality of television program transmissions;</p> <p>a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned;</p> <p>a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and</p> <p>a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 22
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 22
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 22
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	<p>decryption.</p>
---	--------------------

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 22
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 22
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 22
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 22
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned;</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and

a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 22
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>22. A television subscriber station comprising:</p> <p>a receiver for receiving a plurality of television program transmissions;</p> <p>a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned;</p> <p>a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and</p> <p>a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 22
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>22. A television subscriber station comprising:</p> <p>a receiver for receiving a plurality of television program transmissions;</p> <p>a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned;</p> <p>a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and</p> <p>a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 22
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>22. A television subscriber station comprising: a receiver for receiving a plurality of television program transmissions; a tuner for tuning said receiver to a selected one of the plurality of television program transmissions and of informing a processor of the selected transmission to which said receiver is tuned; a decryptor operatively connected to said receiver for receiving, decrypting, and outputting some of said selected television program transmission; and a processor operatively connected to said tuner and said decryptor, for receiving information transmitted in a selected program transmission, locating or identifying information of an instruct-to-decrypt signal associated with said selected transmission, and identifying and transferring to said decryptor a signal needed for decryption, said processor being programmed with or preinformed of the technique for identifying information of said signal needed for decryption.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 23
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>23. A television subscriber station comprising:</p> <p>a receiver for receiving an encrypted television programming transmission;</p> <p>a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal;</p> <p>a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 23
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>23. A television subscriber station comprising:</p> <p>a receiver for receiving an encrypted television programming transmission;</p> <p>a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal;</p> <p>a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 23
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>23. A television subscriber station comprising: a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 23
<p>84. <u>A method of delivering a video presentation at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p style="padding-left: 40px;">transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>23. A television subscriber station comprising: a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 23
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>23. A television subscriber station comprising: a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 23
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>23. A television subscriber station comprising: a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 23
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>23. A television subscriber station comprising: a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

<p>least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 23
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>23. A television subscriber station comprising:</p> <p style="padding-left: 20px;">a receiver for receiving an encrypted television programming transmission;</p> <p style="padding-left: 20px;">a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal;</p> <p style="padding-left: 20px;">a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 23
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>23. A television subscriber station comprising:</p> <p>a receiver for receiving an encrypted television programming transmission;</p> <p>a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal;</p> <p>a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 23
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>23. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 23
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>23. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 23
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>23. A television subscriber station comprising: a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 23
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>23. A television subscriber station comprising:</p> <p>a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 23
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>23. A television subscriber station comprising:</p> <p>a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>television programming transmission in response to an instruct-to-decrypt signal;</p> <p>a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 23
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>23. A television subscriber station comprising:</p> <p>a receiver for receiving an encrypted television programming transmission;</p> <p>a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal;</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 23
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>23. A television subscriber station comprising:</p> <p>a receiver for receiving an encrypted television programming transmission;</p> <p>a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal;</p> <p>a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 23
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>23. A television subscriber station comprising:</p> <p>a receiver for receiving an encrypted television programming transmission;</p> <p>a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal;</p> <p>a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 23
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>23. A television subscriber station comprising: a receiver for receiving an encrypted television programming transmission; a decryptor operatively connected to said detector for decrypting the video portion of said encrypted television programming transmission in response to an instruct-to-decrypt signal; a controller operatively connected to said detector for controlling the manner by which said station locates said signal; and a memory device operatively connected to said controller for holding information of said instruct-to-decrypt signal.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 24
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p>detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p>processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 24
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said</p>

<p>said at least one receiver station from a first remote transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p style="padding-left: 20px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 20px;">receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p style="padding-left: 20px;">transferring said at least one control signal to said transmitter; and</p> <p style="padding-left: 20px;">transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p style="padding-left: 20px;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p style="padding-left: 20px;">transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p style="padding-left: 20px;">receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p style="padding-left: 20px;">detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p style="padding-left: 20px;">processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	---

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 24
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p style="padding-left: 20px;"><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p style="padding-left: 20px;">receiving, at said origination transmitter station, at</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p style="padding-left: 20px;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-</p>

<p>least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p>detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p>processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	--

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 24
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station;</p> <p>delivering said video to a transmitter;</p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p>transferring said first discrete signal to said transmitter; and</p> <p>transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p>detecting data of said plurality of signal types and transferring said data to said processor; and</p>

	processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.
--	--

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 24
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p>detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p>processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 24
-----------------------	-----------------------------------

<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p style="padding-left: 20px;">transferring said at least said first discrete signal to at least one transmitter;</p> <p style="padding-left: 20px;"><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p style="padding-left: 20px;">transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p style="padding-left: 20px;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p style="padding-left: 20px;">transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p style="padding-left: 20px;">receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p style="padding-left: 20px;">detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p style="padding-left: 20px;">processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 24
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and</p>

<p>method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p>detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p>processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	--

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 24
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said</p>

<p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p>detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p>processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	---

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 24
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission</p>

<p><u>on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>that contains a plurality of signal types; receiving said programming transmission and transferring at least a portion of said transmission to said detector; detecting data of said plurality of signal types and transferring said data to said processor; and processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	---

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 24
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of: programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing; transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types; receiving said programming transmission and transferring at least a portion of said transmission to said detector; detecting data of said plurality of signal types and transferring said data to said processor; and processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information</p>

	of said signal.
--	-----------------

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 24
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p style="padding-left: 40px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p style="padding-left: 40px;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p style="padding-left: 40px;">transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p style="padding-left: 40px;">receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p style="padding-left: 40px;">detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p style="padding-left: 40px;">processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 24
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of</p>

<p>detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and transferring at least a portion of said transmission to said detector;</p> <p>detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p>processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	--

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 24
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p>receiving a video image at a transmitter station;</p> <p>delivering said video image to a transmitter;</p> <p><u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission</p>

<p><u>signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>in varying locations or in a varying pattern of timing, said method comprising the steps of: programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing; transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types; receiving said programming transmission and transferring at least a portion of said transmission to said detector; detecting data of said plurality of signal types and transferring said data to said processor; and processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	--

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 24
<p>167. A method of outputting a video graphic presentation at a receiver station including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, said at least one processor</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of: programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing; transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p>

<p>instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>receiving said programming transmission and transferring at least a portion of said transmission to said detector; detecting data of said plurality of signal types and transferring said data to said processor; and processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 24
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u> transferring said at least one discrete signal to a transmitter;</p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing; transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types; receiving said programming transmission and transferring at least a portion of said transmission to said detector; detecting data of said plurality of signal types and transferring said data to said processor; and processing said data to locate or identify an instruct-</p>

<p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	--

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 24
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and</p>

<p><u>full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>transferring at least a portion of said transmission to said detector;</p> <p>detecting data of said plurality of signal types and transferring said data to said processor; and</p> <p>processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 24
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing;</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types;</p> <p>receiving said programming transmission and transferring at least a portion of said transmission to</p>

<p><u>complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.</p>	<p>said detector; detecting data of said plurality of signal types and transferring said data to said processor; and processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	---

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 24
<p>179. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said</u></p>	<p>24. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, said method comprising the steps of: programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing; transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types; receiving said programming transmission and transferring at least a portion of said transmission to said detector; detecting data of said plurality of signal types and transferring said data to said processor; and processing said data to locate or identify an instruct-to-decrypt signal, and identifying or locating at least one instruct-to-decrypt signal, thereby to enable said station to decrypt at least a part of an encrypted</p>

<u>second completed full-screen video graphic image</u> <u>and only a portion of said first completed full-screen</u> <u>video graphic image,</u> wherein said method delivers said video graphic presentation.	programming transmission in response to information of said signal.
---	--

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 25
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 25
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, <u>said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image</u></p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and</p>

<p><u>containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 25
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p>

<p>communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 25
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p>receiving video at a transmitter station;</p> <p>delivering said video to a transmitter;</p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p>transferring said first discrete signal to said transmitter; and</p> <p>transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said</p>

	data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.
--	--

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 25
<p>93. <u>A method of outputting a video presentation at a receiver station</u>, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p style="padding-left: 20px;">passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p style="padding-left: 20px;">transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 25
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p><u>transferring said at least said first discrete signal to at least one transmitter;</u></p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p><u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p><u>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</u></p>

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 25
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said</u></p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and</p>

<p>method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 25
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in</u></p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are</p>

<p><u>conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>transmitted in varying locations or in a varying pattern of timing, said method comprising the step of: transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 25
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal; passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing; responding to said at least one processor instruction</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p>

<p>at said receiver station based on said step of passing said at least one processor instruction; <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 25
<p>143. <u>A method of outputting a video presentation at a receiver station</u> including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of: transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or</p>

	identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.
--	---

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 25
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable <u>processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p style="padding-left: 40px;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 40px;">receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p style="padding-left: 40px;">transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 25
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 25
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response</p>

<p>said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and</p> <p style="padding-left: 40px;">transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p style="padding-left: 40px;">transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 25
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p style="padding-left: 40px;">receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p style="padding-left: 40px;">passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p style="padding-left: 40px;">displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p style="padding-left: 40px;">detecting said at least a first discrete signal of said downloadable code;</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-</p>

<p>passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image;</u> and <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of: transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 25
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image,</u> wherein said first completed full-screen video graphic</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are</p>

<p><u>image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said at least one discrete signal and said one or more control signals,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 25
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission</p>

<p>at said video monitor; <u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.</p>	<p>in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of: transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 25
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of: receiving a first completed full-screen video graphic image at a transmitter station, said first completed</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying</p>

<p>full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of:</p> <p>transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	--

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 25
<p>179. <u>A method of outputting a video graphic presentation at a receiver station</u> including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p>	<p>25. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing and with said processor being programmed with information of a procedure for identifying an instruct-</p>

<p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> passing, to said video monitor based on said step of responding to at least one processor instruction, <u>only a portion of a second completed full-screen video graphic image;</u> and <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, said method comprising the step of: transmitting instruct-to-decrypt signals to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, thereby to enable a subscriber station to receive said programming transmission and transfer at least a portion of said transmission to said detector, detect data of said plurality of signal types and transfer said data to said processor, process said data to locate or identify an instruct-to-decrypt signal, identify or locate at least one instruct-to-decrypt signal, and decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations in an operating environment of a transmitter station.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 26
<p>56. A method for receiving and processing data for use with an interactive video apparatus, <u>said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p>communicating one of said at least said first request and a second request to a remote data source;</p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u> and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 26
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote</u></p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying</p>

<p>transmitter station, <u>said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image,</u> said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image,</u> said downloadable processor instructions having at said at least one receiver station a target processor to process data;</p> <p style="padding-left: 2em;">transferring said downloadable processor instructions to a transmitter;</p> <p style="padding-left: 2em;">receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</p> <p style="padding-left: 2em;">transferring said at least one control signal to said transmitter; and</p> <p style="padding-left: 2em;">transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p style="padding-left: 2em;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 26
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal,</u> said method comprising the steps of:</p> <p style="padding-left: 2em;">receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p style="padding-left: 2em;"><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video</u></p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing,</p>

<p><u>presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 26
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving video at a transmitter station;</p> <p style="padding-left: 40px;">delivering said video to a transmitter;</p> <p style="padding-left: 40px;"><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image</u></p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said</p>

<p><u>for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>plurality of signal types, and transferring said data to said processor, said method comprising the step of: programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 26
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of: receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to</u></p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of: programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to</p>

<p><u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to- decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	--

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 26
<p>110. <u>A method of outputting a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u> <u>at least one processor instruction has at said at least</u> <u>one of said plurality of receiver stations a target</u> <u>processor to process data;</u></p> <p><u>transferring said at least said first discrete signal to</u> <u>at least one transmitter;</u></p> <p><u>receiving said at least one control signal at said at</u> <u>least one transmitter station, wherein said at least one</u> <u>control signal is operative at said at least one of said</u> <u>plurality of receiver stations to organize said</u> <u>information in said first and second discrete signals</u> <u>into said at least one processor instruction; and</u></p> <p><u>transferring said at least one control signal to said at</u> <u>least one transmitter, and transmitting at least one</u> <u>information transmission containing said at least said</u> <u>first discrete signal and said at least one control signal.</u></p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to- decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to- decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 26
<p>116. <u>A method of delivering a video presentation</u> at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p style="padding-left: 2em;"><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p style="padding-left: 2em;">receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p style="padding-left: 2em;">transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p style="padding-left: 2em;">transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p style="padding-left: 2em;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 26
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of</p>

<p>processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p style="padding-left: 20px;">transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	<p>an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p style="padding-left: 20px;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 26
-----------------------	-----------------------------------

<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p style="padding-left: 20px;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	---

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 26
<p>143. A method of outputting a video presentation at a receiver station including:</p> <p style="padding-left: 20px;">receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p style="padding-left: 20px;">passing said received video image to an output device for delivery to a user;</p> <p style="padding-left: 20px;">detecting said at least one first discrete signal;</p> <p style="padding-left: 20px;">passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p style="padding-left: 20px;">organizing said information contained in said at</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said</p>

<p>least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</p> <p> responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</p> <p> generating a signal based on said processor instructions; and</p> <p> outputting at least a portion of said video presentation based on said generated signal.</p>	<p>decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p> programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
--	--

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 26
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <p> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p> transferring said downloadable processor instructions to a transmitter;</p> <p> receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p>

<p>receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and <u>wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 26
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying</p>

	locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.
--	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 26
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of: programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 26
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <ul style="list-style-type: none"> programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 26
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p style="padding-left: 2em;"><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p style="padding-left: 2em;">transferring said at least one discrete signal to a transmitter;</p> <p style="padding-left: 2em;"><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u></p> <p style="padding-left: 2em;">transferring said one or more control signals to said transmitter; and</p> <p style="padding-left: 2em;">transmitting a transmission comprising said at least</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p style="padding-left: 2em;">programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

<p>one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station:

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 26
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.</p>

<p>processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 26
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p>	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <p>programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming</p>

transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.	transmission in response to information of said signal.
---	---

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 26
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen</u> 	<p>26. A method for causing decryption of television or computer programming at a station that includes a decryptor for receiving and decrypting at least part of an encrypted programming transmission in response to information of an instruct-to-decrypt signal; a digital detector for detecting data of a plurality of signal types in a mass medium programming transmission and transferring said data to a processor; and a processor operatively connected to said decryptor and said detector for locating or identifying an instruct-to-decrypt signal in said data and transferring information of said signal to said decryptor, with instruct-to-decrypt signals being of a signal type and being transmitted in said transmission in varying locations or in a varying pattern of timing, with instruct-to-decrypt signals being transmitted to said station in varying locations or a varying pattern of timing in a mass medium programming transmission that contains a plurality of signal types, and with said station receiving said programming transmission, combining at least a portion of said transmission to said detector, detecting data of said plurality of signal types, and transferring said data to said processor, said method comprising the step of:</p> <ul style="list-style-type: none"> programming said processor with information of a procedure for identifying an instruct-to-decrypt signal in a plurality of signal types or for locating instruct-to-decrypt signals that are transmitted in varying locations or in a varying pattern of timing, thereby to enable said station to process said data to locate or identify an instruct-to-decrypt signal, to enable said station to identify or locate at least one instruct-to-decrypt signal, and to enable said station to decrypt at least a part of an encrypted programming transmission in response to information of said signal.

<u>video graphic image</u> wherein said method delivers said video graphic presentation.	
--	--

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 27
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>27. A subscriber station comprising:</p> <p>a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices;</p> <p>means for transferring said information from one of said detectors to a processor; and</p> <p>a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 27
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>27. A subscriber station comprising:</p> <p>a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices;</p> <p>means for transferring said information from one of said detectors to a processor; and</p> <p>a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 27
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>27. A subscriber station comprising: a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 27
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>27. A subscriber station comprising:</p> <p>a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices;</p> <p>means for transferring said information from one of said detectors to a processor; and</p> <p>a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 27
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>27. A subscriber station comprising:</p> <p>a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices;</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 27
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>27. A subscriber station comprising: a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 27
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal; receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>27. A subscriber station comprising: a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 27
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>27. A subscriber station comprising:</p> <p>a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices;</p> <p>means for transferring said information from one of said detectors to a processor; and</p> <p>a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 27
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>27. A subscriber station comprising:</p> <p style="padding-left: 20px;">a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices;</p> <p style="padding-left: 20px;">means for transferring said information from one of said detectors to a processor; and</p> <p style="padding-left: 20px;">a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 27
<p>143. <u>A method of outputting a video presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information</u>, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>27. A subscriber station comprising:</p> <ul style="list-style-type: none"> a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 27
<p>152. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation</u> and have a target processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>27. A subscriber station comprising:</p> <ul style="list-style-type: none"> a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 27
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>27. A subscriber station comprising: a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 27
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>27. A subscriber station comprising: a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 27
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>27. A subscriber station comprising: a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 27
171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is	27. A subscriber station comprising: a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

specific devices;

means for transferring said information from one of said detectors to a processor; and

a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 27
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>27. A subscriber station comprising:</p> <p>a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices;</p> <p>means for transferring said information from one of said detectors to a processor; and</p> <p>a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 27
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>27. A subscriber station comprising:</p> <p>a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices;</p> <p>means for transferring said information from one of said detectors to a processor; and</p> <p>a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 27
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>27. A subscriber station comprising: a plurality of detectors, each operatively connected to a specific one of a programming receiver device, a display device, a storage device, a processing device or a transmission device for detecting information that identifies specific programming to be received, displayed, stored, processed or transmitted by said specific devices; means for transferring said information from one of said detectors to a processor; and a processor connected to said means for transferring for receiving said information and assembling or storing records that contain statistics on programming availability, use or usage at said station.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 28
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>28. A television subscriber or computer user station comprising:</p> <p>a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p>means for transferring said information from one of said decoder to a processor; and</p> <p>a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 28
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>28. A television subscriber or computer user station comprising:</p> <p>a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p>means for transferring said information from one of said decoder to a processor; and</p> <p>a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 28
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p style="padding-left: 20px;"><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p style="padding-left: 20px;">receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</p> <p style="padding-left: 20px;">transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>28. A television subscriber or computer user station comprising:</p> <p style="padding-left: 20px;">a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p style="padding-left: 20px;">means for transferring said information from one of said decoder to a processor; and</p> <p style="padding-left: 20px;">a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 28
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>28. A television subscriber or computer user station comprising:</p> <ul style="list-style-type: none"> a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device; means for transferring said information from one of said decoder to a processor; and a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 28
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>28. A television subscriber or computer user station comprising:</p> <ul style="list-style-type: none"> a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>device; means for transferring said information from one of said decoder to a processor; and a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 28
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>28. A television subscriber or computer user station comprising: a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device; means for transferring said information from one of said decoder to a processor; and a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 28
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction,</u> said method comprising the steps of: <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>28. A television subscriber or computer user station comprising: a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device; means for transferring said information from one of said decoder to a processor; and a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

<p>least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 28
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>28. A television subscriber or computer user station comprising:</p> <p>a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p>means for transferring said information from one of said decoder to a processor; and</p> <p>a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 28
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>28. A television subscriber or computer user station comprising:</p> <p>a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p>means for transferring said information from one of said decoder to a processor; and</p> <p>a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 28
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal.</p>	<p>28. A television subscriber or computer user station comprising: a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device; means for transferring said information from one of said decoder to a processor; and a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 28
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of: receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>28. A television subscriber or computer user station comprising: a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device; means for transferring said information from one of said decoder to a processor; and a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

<p>instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 28
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p style="padding-left: 20px;"><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p style="padding-left: 20px;">receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</p> <p style="padding-left: 20px;">transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>28. A television subscriber or computer user station comprising:</p> <p style="padding-left: 20px;">a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p style="padding-left: 20px;">means for transferring said information from one of said decoder to a processor; and</p> <p style="padding-left: 20px;">a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 28
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u></p> <p style="padding-left: 40px;">transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>28. A television subscriber or computer user station comprising:</p> <p style="padding-left: 40px;">a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p style="padding-left: 40px;">means for transferring said information from one of said decoder to a processor; and a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 28
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <p style="padding-left: 40px;">receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</p>	<p>28. A television subscriber or computer user station comprising:</p> <p style="padding-left: 40px;">a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating</p>

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image;</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p>means for transferring said information from one of said decoder to a processor; and</p> <p>a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 28
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>28. A television subscriber or computer user station comprising:</p> <p>a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored,</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

processed, transmitted, or outputted by said specific device;

means for transferring said information from one of said decoder to a processor; and

a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 28
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 40px;">receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p style="padding-left: 40px;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 40px;">receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p style="padding-left: 40px;">transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p style="padding-left: 40px;">wherein said method delivers said video graphic presentation.</p>	<p>28. A television subscriber or computer user station comprising:</p> <p style="padding-left: 40px;">a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p style="padding-left: 40px;">means for transferring said information from one of said decoder to a processor; and</p> <p style="padding-left: 40px;">a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 28
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>28. A television subscriber or computer user station comprising:</p> <p>a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device;</p> <p>means for transferring said information from one of said decoder to a processor; and</p> <p>a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 28
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation. 	<p>28. A television subscriber or computer user station comprising:</p> <ul style="list-style-type: none"> a plurality of decoders, each operatively connected to a specific programming receiver, display, storage, processing, transmission, or output device for locating or identifying identifier information that identifies specific programming received, displayed, stored, processed, transmitted, or outputted by said specific device; means for transferring said information from one of said decoder to a processor; and a controller operatively connected to some of said plurality of decoders for instructing a selected one of said decoders how to locate said identifier information.

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 29
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>29. A computer system comprising:</p> <p>a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;</p> <p>a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and</p> <p>a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 29
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>29. A computer system comprising:</p> <p>a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;</p> <p>a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and</p> <p>a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 29
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>29. A computer system comprising: a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 29
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 20px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>29. A computer system comprising:</p> <p style="padding-left: 20px;">a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;</p> <p style="padding-left: 20px;">a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and</p> <p style="padding-left: 20px;">a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 29
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 20px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>29. A computer system comprising:</p> <p style="padding-left: 20px;">a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;</p> <p style="padding-left: 20px;">a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 29
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>29. A computer system comprising: a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction;</u> and transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 29
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction,</u> said method comprising the steps of: <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>29. A computer system comprising: a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.	
--	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 29
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p style="padding-left: 40px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 40px;">transferring said at least one instruct signal to at least one transmitter;</p> <p style="padding-left: 40px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</p>	<p>29. A computer system comprising:</p> <p style="padding-left: 40px;">a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;</p> <p style="padding-left: 40px;">a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and</p> <p style="padding-left: 40px;">a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 29
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>29. A computer system comprising:</p> <p>a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;</p> <p>a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and</p> <p>a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 29
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>29. A computer system comprising: a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 29
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor</p>	<p>29. A computer system comprising: a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 29
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of: <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>29. A computer system comprising: a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 29
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <p><u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>29. A computer system comprising:</p> <ul style="list-style-type: none"> a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 29
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <p><u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>29. A computer system comprising:</p> <ul style="list-style-type: none"> a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 29
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>29. A computer system comprising: a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

computer and a storage; and

a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 29
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image;</u> and</p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>29. A computer system comprising:</p> <p>a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;</p> <p>a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and</p> <p>a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 29
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>29. A computer system comprising:</p> <p>a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions;</p> <p>a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and</p> <p>a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 29
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>29. A computer system comprising: a detector operatively connected to a mass medium receiver for detecting information in a selected broadcast or cablecast transmission, said information including computer control instructions; a transmission device operatively connected to said detector for transmitting control instructions to a computer and a storage; and a processor operatively connected to said transmission device for inputting said detected information selectively to said computer or said storage.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 30
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>30. A mass medium subscriber station comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals;</p> <p>a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control.</p> <p>a plurality of controlled apparatus; and</p> <p>a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 30
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>30. A mass medium subscriber station comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals;</p> <p>a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control.</p> <p>a plurality of controlled apparatus; and</p> <p>a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 30
<p>80. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>30. A mass medium subscriber station comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 30
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>30. A mass medium subscriber station comprising:</p> <ul style="list-style-type: none"> a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 30
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete 	<p>30. A mass medium subscriber station comprising:</p> <ul style="list-style-type: none"> a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals;

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 30
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u> <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>30. A mass medium subscriber station comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>one of said controlled apparatus on the basis of said received control signals.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 30
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>30. A mass medium subscriber station comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 30
<p>123. <u>A method of delivering a video presentation at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>30. A mass medium subscriber station comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals;</p> <p>a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control.</p> <p>a plurality of controlled apparatus; and</p> <p>a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 30
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>30. A mass medium subscriber station comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals;</p> <p>a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control.</p> <p>a plurality of controlled apparatus; and</p> <p>a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 30
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing; generating a signal based on said processor instructions; and outputting at least a portion of said video presentation based on said generated signal. 	<p>30. A mass medium subscriber station comprising:</p> <ul style="list-style-type: none"> a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 30
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station,</u> said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>30. A mass medium subscriber station comprising:</p> <ul style="list-style-type: none"> a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 30
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>30. A mass medium subscriber station comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 30
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station. 	<p>30. A mass medium subscriber station comprising:</p> <ul style="list-style-type: none"> a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 30
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full- 	<p>30. A mass medium subscriber station comprising:</p> <ul style="list-style-type: none"> a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said

<p>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</p> <p>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal of said downloadable code;</p> <p>passing said at least a first discrete signal of said downloadable code to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p>responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>selected broadcast or cablecast transmission, said information including subscriber station environment control signals;</p> <p>a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control.</p> <p>a plurality of controlled apparatus; and</p> <p>a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 30
<p>171. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</p>	<p>30. A mass medium subscriber station comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

control signals;

a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control.

a plurality of controlled apparatus; and

a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 30
<p>175. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</p> <p>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>30. A mass medium subscriber station comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals;</p> <p>a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control.</p> <p>a plurality of controlled apparatus; and</p> <p>a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 30
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>30. A mass medium subscriber station comprising:</p> <p>a mass medium receiver for receiving a selected broadcast or cablecast transmission;</p> <p>a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals;</p> <p>a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control.</p> <p>a plurality of controlled apparatus; and</p> <p>a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 30
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> responding to at least one processor instruction at said receiver station, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> wherein said method delivers said video graphic presentation.</p>	<p>30. A mass medium subscriber station comprising: a mass medium receiver for receiving a selected broadcast or cablecast transmission; a detector operatively connected to said mass medium receiver for detecting information in said selected broadcast or cablecast transmission, said information including subscriber station environment control signals; a processor for receiving information detected by said detector identifying said environment controller signals, and outputting said signals to a specific control. a plurality of controlled apparatus; and a plurality of controllers each operatively connected to said processor and one of said controlled apparatus, each of said controllers receiving selected ones of said control signals from said processor and controlling one of said controlled apparatus on the basis of said received control signals.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 31
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 31
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver</p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for</p>

<p>stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said <u>video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u></p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u></p> <p>transferring said at least one control signal to said transmitter; and</p> <p>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 31
80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal,	31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor

<p>said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u></p> <p><u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal;</u> and</p> <p>transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
---	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 31
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein <u>at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a</p>

<p><u>capable of providing said at least one processor instruction</u>, said method comprising the steps of:</p> <p>receiving video at a transmitter station;</p> <p>delivering said video to a transmitter;</p> <p>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</p> <p>transferring said first discrete signal to said transmitter; and</p> <p>transmitting said video and said first discrete signal to said at least one receiver station.</p>	<p>plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
---	---

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 31
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one</p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a</p>

<p>information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 31
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an</p>

<p><u>said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 31
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction,</u> said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a</p>

<p><u>wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>control instruction that is addressed to a specific one of said plurality of controllers; receiving said transmission at said station and transferring information of said transmission to said detector; detecting data of said control instruction in said information and transferring said data to said first processor; assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data; transferring said message information to said transmission; and processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 31
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device</u>, said method comprising the steps of: receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image; transferring said at least one instruct signal to at</p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of: transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers; receiving said transmission at said station and</p>

<p>least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u></p>	<p>transferring information of said transmission to said detector; detecting data of said control instruction in said information and transferring said data to said first processor; assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data; transferring said message information to said transmission; and processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
--	---

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 31
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of: receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal; detecting said at least a first discrete signal and said at least one control signal in said information transmission; passing said detected at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of: transmitting in a point to multipoint transmission a</p>

<p><u>processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>control instruction that is addressed to a specific one of said plurality of controllers; receiving said transmission at said station and transferring information of said transmission to said detector; detecting data of said control instruction in said information and transferring said data to said first processor; assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data; transferring said message information to said transmission; and processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
---	--

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 31
<p>143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of: transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers; receiving said transmission at said station and transferring information of said transmission to said</p>

	<p>detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
--	---

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 31
<p>152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p>

<p><u>downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 31
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u></p> <p><u>and</u></p> <p>transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or</p>

	changing said data; transferring said message information to said transmission; and processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.
--	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 31
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p style="padding-left: 40px;">transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers; receiving said transmission at said station and transferring information of said transmission to said detector; detecting data of said control instruction in said information and transferring said data to said first processor; assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data; transferring said message information to said transmission; and</p>

	processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.
--	---

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 31
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing</u> 	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <ul style="list-style-type: none"> transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers; receiving said transmission at said station and transferring information of said transmission to said detector; detecting data of said control instruction in said information and transferring said data to said first processor; assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data; transferring said message information to said transmission; and processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable

screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,
wherein said method delivers said video graphic presentation.

said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 31
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor,</p>

<p><u>contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	<p>storage or output device in accordance with said control instruction.</p>
--	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 31
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said</p>

<p><u>only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> <u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u> transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.</p>	<p>control instruction by selectively discarding some of said data, adding information to said data, or changing said data; transferring said message information to said transmission; and processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
---	---

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 31
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of: receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor; delivering said received first completed full-screen video graphic image to a transmitter; <u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of: transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers; receiving said transmission at said station and transferring information of said transmission to said detector;</p>

<p><u>filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p>transferring said one or more instruct signals to said transmitter; and</p> <p>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</p> <p>wherein said method delivers said video graphic presentation.</p>	<p>detecting data of said control instruction in said information and transferring said data to said first processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
---	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 31
<p>179. A method of outputting a video graphic presentation at a receiver station including:</p> <p>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</p> <p>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</p> <p>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</p> <p>detecting said at least a first discrete signal;</p> <p>passing said at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u></p> <p><u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u></p>	<p>31. A method for selectively controlling apparatus at a subscriber station that includes a receiver for receiving a point to multipoint programming transmission, a detector for detecting control instructions in said transmission, a first processor operatively connected to said detector for selectively assembling information of said control instructions, a means for transferring control instructions to a plurality of controllers, and a second processor operatively connected to said means for transferring for inputting control instructions selectively to a specific one of said plurality of controllers, with each controller operatively connected to a specific one of a plurality of devices comprising a tuner, a decryptor, a transfer, a computer, a processor, a storage device, an output device, each controller controlling at least one of said devices, said method comprising the steps of:</p> <p>transmitting in a point to multipoint transmission a control instruction that is addressed to a specific one of said plurality of controllers;</p> <p>receiving said transmission at said station and transferring information of said transmission to said detector;</p> <p>detecting data of said control instruction in said information and transferring said data to said first</p>

<p><u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u></p> <p><u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u></p> <p>wherein said method delivers said video graphic presentation.</p>	<p>processor;</p> <p>assembling local message information of said control instruction by selectively discarding some of said data, adding information to said data, or changing said data;</p> <p>transferring said message information to said transmission; and</p> <p>processing said message information at said second processor and inputting said information to a selected one of said plurality of controllers, thereby to enable said controller to control its associated tuner, decryptor, transfer device, computer, processor, storage or output device in accordance with said control instruction.</p>
--	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 32
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 32
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to</p>

<p><u>second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>
--	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 32
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said</p>	<p>32. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions; a storage device for storing hold-and-compare signals; a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller; a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and a controller operatively connected to said means for comparing and said tuner for selecting a specific data</p>

instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.	transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.
--	--

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 32
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 32
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation</p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals</p>

<p>comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>
---	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 32
<p>110. <u>A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-</p>

<p><u>information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>
---	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 32
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data</p>

<p><u>signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 32
<p>123. <u>A method of delivering a video presentation</u> at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station</u>, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

<p><u>information with information contained in a second discrete signal at said at least one of said plurality of receiver stations</u>, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 32
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p style="padding-left: 20px;">receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p style="padding-left: 20px;">detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p style="padding-left: 20px;">passing said detected at least a first discrete signal to at least one processor;</p> <p style="padding-left: 20px;"><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p style="padding-left: 20px;">passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p style="padding-left: 20px;">responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p style="padding-left: 20px;"><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p style="padding-left: 20px;"><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>32. A data receiver system comprising:</p> <p style="padding-left: 20px;">a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p style="padding-left: 20px;">a storage device for storing hold-and-compare signals;</p> <p style="padding-left: 20px;">a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p style="padding-left: 20px;">a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p style="padding-left: 20px;">a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p style="padding-left: 20px;">a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 32
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <p>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</p> <p>passing said received video image to an output device for delivery to a user;</p> <p>detecting said at least one first discrete signal;</p> <p>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</p> <p><u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u></p> <p>responding, at said processor, to <u>processor instructions comprising said organized information,</u> based on said step of organizing;</p> <p>generating a signal based on said processor instructions; and</p> <p><u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 32
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification</p>

<p>processor to process data, <u>said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 32
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data</p>

<p><u>local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>
--	---

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 32
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>32. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions; a storage device for storing hold-and-compare signals; a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller; a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 32
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u> 	<p>32. A data receiver system comprising:</p> <ul style="list-style-type: none"> a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions; a storage device for storing hold-and-compare signals; a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller; a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 32
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:</u></p> <p><u>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</u></p> <p><u>transferring said at least one discrete signal to a transmitter;</u></p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first</u></p>	<p>32. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a storage device for storing hold-and-compare signals;</p> <p>a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and</p> <p>a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

<p><u>completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, <u>wherein said method delivers said video graphic presentation.</u></p>	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 32
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u> <u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> <u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter</u></p>	<p>32. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions; a storage device for storing hold-and-compare signals; a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller; a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

<p><u>station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u> <u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	
--	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 32
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u> <u>delivering said received first completed full-screen video graphic image to a transmitter;</u> <u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic</u></p>	<p>32. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions; a storage device for storing hold-and-compare signals; a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller; a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.</p>

<u>image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.	
---	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 32
179. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal; responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing; passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said	32. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content in a plurality of concurrent broadcast or cablecast data transmissions; a storage device for storing hold-and-compare signals; a means operatively connected to said first receiver and said storage for receiving said identification signals and said hold-and-compare signals, comparing said identification signals to said hold-and-compare signals, and conveying the information identified by said comparison to a controller; a second receiver operatively connected to a data processor or a data output for receiving selected data transmissions and directing said data transmissions to said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmissions; and a controller operatively connected to said means for comparing and said tuner for selecting a specific data transmission on the basis of information conveyed by said means for comparing and instructing said tuner to cause said second receiver to receive said selected data transmissions.

<u>second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image, wherein said method delivers said video graphic presentation.</u>	
---	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 33
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p>and</p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>33. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 33
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>33. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

<p>processor instructions having at said at least one receiver station a target processor to process data; transferring said downloadable processor instructions to a transmitter; receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation; transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	
---	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 33
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.</p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 33
<p>84. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals</u> and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</p> <p style="padding-left: 40px;"><u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>33. A data receiver system comprising:</p> <p style="padding-left: 40px;">a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions;</p> <p style="padding-left: 40px;">a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output;</p> <p style="padding-left: 40px;">a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and</p> <p style="padding-left: 40px;">a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 33
<p>93. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p style="padding-left: 40px;">receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</p>	<p>33. A data receiver system comprising:</p> <p style="padding-left: 40px;">a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions;</p> <p style="padding-left: 40px;">a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing</p>

<p>signal and at least one control signal; detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission; passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor; <u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u> responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction; <u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 33
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of: <u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said</u></p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> transferring said at least said first discrete signal to at least one transmitter; <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>said second receiver to receive said selected data transmission.</p>
--	---

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 33
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction; transferring said at least one control signal to said at</p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

<p>least one origination transmitter before a specific time; and transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 33
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u> <u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u> transferring said at least one instruct signal to at least one transmitter; <u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

<p>be effective at said at least one of said plurality of receiver stations; and</p> <p>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 33
<p>142. <u>A method of outputting a video presentation</u> at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station; said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p>passing at least one processor instruction from or within said at least one processor, <u>said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction;</u> and</p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>33. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 33
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u></p> <ul style="list-style-type: none"> receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> responding, at said processor, to <u>processor instructions comprising said organized information</u>, based on said step of organizing; generating a signal based on said processor instructions; and <u>outputting at least a portion of said video presentation based on said generated signal.</u> 	<p>33. A data receiver system comprising:</p> <ul style="list-style-type: none"> a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 33
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u></p> <ul style="list-style-type: none"> receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions; transferring said downloadable processor 	<p>33. A data receiver system comprising:</p> <ul style="list-style-type: none"> a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.

<p>instructions to a transmitter; <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	
--	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 33
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 33
<p>162. <u>A method of delivering a video presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, <u>said code comprised of information contained in each of said plurality of discrete signals</u>, said method comprising the steps of: <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 33
<p>167. <u>A method of outputting a video graphic presentation</u> at a receiver station including: <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions;</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 33
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

of said plurality of data transmission and directing said one of said data processor or output;

a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and

a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 33
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>33. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 33
<p>177. <u>A method of delivering a video graphic presentation</u> at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>33. A data receiver system comprising:</p> <p>a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions;</p> <p>a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 33
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>33. A data receiver system comprising: a first receiver for receiving identification signals that identify specific information content of a specific one or ones of a plurality of concurrent broadcast or cablecast data transmissions; a second receiver operatively connected to a data processor or a data output for receiving a selected one of said plurality of data transmission and directing said one of said data processor or output; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected data transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, receiving said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected data transmission.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 34
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>34. A television receiver system comprising:</p> <p>a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p> <p>a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 34
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>34. A television receiver system comprising:</p> <p>a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p> <p>a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 34
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 34
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>34. A television receiver system comprising:</p> <p>a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p> <p>a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 34
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>34. A television receiver system comprising:</p> <p>a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p> <p>a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 34
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>cause said second receiver to receive said selected transmission.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 34
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 34
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>34. A television receiver system comprising:</p> <p style="padding-left: 20px;">a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p> <p style="padding-left: 20px;">a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor;</p> <p style="padding-left: 20px;">a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and</p> <p style="padding-left: 20px;">a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 34
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u></p> <p><u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u></p> <p><u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u></p> <p><u>passing said detected at least a first discrete signal to at least one processor;</u></p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>34. A television receiver system comprising:</p> <p>a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p> <p>a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 34
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 34
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 34
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 34
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 34
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 34
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

of said plurality of television program transmission and directing said one to said data processor;

a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and

a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 34
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>34. A television receiver system comprising:</p> <p>a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p> <p>a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 34
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>34. A television receiver system comprising:</p> <p>a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions;</p> <p>a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor;</p> <p>a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and</p> <p>a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 34
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>34. A television receiver system comprising: a first receiver for receiving identification signals that identifying specific information content of a specific one of a plurality of concurrent broadcast or cablecast television program transmissions; a second receiver operatively connected to a television data processor for receiving a selected one of said plurality of television program transmission and directing said one to said data processor; a tuner operatively connected to said second receiver for causing said second receiver to receive said selected television program transmission; and a processor operatively connected to said first receiver and said tuner for storing hold-and-compare signals, locating or identifying said identification signals, comparing said identification signals to hold-and-compare signals, and instructing said tuner to cause said second receiver to receive said selected transmission.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 35
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>35. A television subscriber station comprising:</p> <p>a converter for receiving a multichannel television transmission;</p> <p>a tuner operatively connected to said converter for selecting a specific television channel;</p> <p>a television receiver or display device for displaying programming of a channel specified by said tuner; and</p> <p>a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 35
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>35. A television subscriber station comprising:</p> <p>a converter for receiving a multichannel television transmission;</p> <p>a tuner operatively connected to said converter for selecting a specific television channel;</p> <p>a television receiver or display device for displaying programming of a channel specified by said tuner; and</p> <p>a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 35
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 35
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 35
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u> <u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 35
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 35
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 35
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>35. A television subscriber station comprising:</p> <p>a converter for receiving a multichannel television transmission;</p> <p>a tuner operatively connected to said converter for selecting a specific television channel;</p> <p>a television receiver or display device for displaying programming of a channel specified by said tuner; and</p> <p>a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 35
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 35
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 35
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 35
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal;</u> <u>and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 35
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 35
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel;</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 35
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner;</p>

programmed to process said at least one processor instruction, wherein said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

and

a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 35
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>35. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 35
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>35. A television subscriber station comprising:</p> <p>a converter for receiving a multichannel television transmission;</p> <p>a tuner operatively connected to said converter for selecting a specific television channel;</p> <p>a television receiver or display device for displaying programming of a channel specified by said tuner; and</p> <p>a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 35
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>35. A television subscriber station comprising: a converter for receiving a multichannel television transmission; a tuner operatively connected to said converter for selecting a specific television channel; a television receiver or display device for displaying programming of a channel specified by said tuner; and a controller operatively connected to said tuner for storing information of a selected television program unit and causing said tuner to select a television transmission containing programming of said selected television unit at a specific time.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 38
<p>56. A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying <u>a video presentation comprising a locally generated image and an image received from a remote video source</u>, said method comprising the steps of:</p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 38
<p>75. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said <u>video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image</u>, said method comprising the steps of:</p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p>

<p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> transferring said downloadable processor instructions to a transmitter; <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> transferring said at least one control signal to said transmitter; and transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</p>	<p>inputting at least part of a programming transmission to said processor; detecting in said part identification data that identifies a specific television or radio program unit; inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>
--	---

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 38
<p>80. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of: receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station; <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> receiving, at said origination transmitter station, at least one control signal that, at the remote</p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of: inputting to said controller identification information of at least one specified television or radio program unit; inputting at least part of a programming transmission to said processor; detecting in said part identification data that identifies a specific television or radio program unit; inputting information of said identification data to</p>

intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and transmitting said at least one control signal from said origination transmitter before a specific time.	said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.
---	---

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 38
<p>84. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, <u>wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction</u>, said method comprising the steps of:</p> <ul style="list-style-type: none"> receiving video at a transmitter station; delivering said video to a transmitter; <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> transferring said first discrete signal to said transmitter; and transmitting said video and said first discrete signal to said at least one receiver station. 	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <ul style="list-style-type: none"> inputting to said controller identification information of at least one specified television or radio program unit; inputting at least part of a programming transmission to said processor; detecting in said part identification data that identifies a specific television or radio program unit; inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 38
<p>93. A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</p> <p>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete signal and at least one control signal;</p> <p>detecting said at least one first discrete signal and said at least one control signal in said at least one information transmission;</p> <p>passing said detected at least one first discrete signal and said detected at least one control signal to at least one processor;</p> <p><u>organizing information contained in said at least one first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating an image to replace only a portion of said video image by processing at least one stored subscriber datum based on said step of responding to said at least one processor instruction; and</u></p> <p><u>outputting said video presentation to a user, said video presentation containing, firstly, said video image and, secondly, said generated image to replace said only said portion of said video image.</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 38
<p>110. A method of outputting a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, each of said plurality of receiver stations being adapted to detect the presence of at least one control signal and programmed to process at least one processor instruction, said method comprising the steps of:</p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller</p>

<p><u>receiving at at least one transmitter station at least a first discrete signal containing information, wherein said at least one processor instruction comprises information organized from said information contained in said first discrete signal and information contained in a second discrete signal, said at least one processor instruction is effective at said at least one of said plurality of receiver stations to generate and output only a portion of said video presentation, said at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u></p> <p>transferring said at least said first discrete signal to at least one transmitter;</p> <p><u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u></p> <p>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</p>	<p>capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 38
<p>116. A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction</u>, said method comprising the steps of:</p> <p><u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that</p>

<p><u>wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u></p> <p>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</p> <p>transferring said at least one control signal to said at least one origination transmitter before a specific time; and</p> <p>transmitting from said at least origination transmitter said first discrete signal and said at least one control signal.</p>	<p>identifies a specific television or radio program unit; inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>
---	---

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 38
<p>123. A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, <u>wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p>transferring said at least one instruct signal to at least one transmitter;</p> <p><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>

<p><u>code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to be effective at said at least one of said plurality of receiver stations; and</u></p> <p><u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u></p>	
---	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 38
<p>142. A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</p> <p>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</p> <p>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</p> <p>passing said detected at least a first discrete signal to at least one processor;</p> <p><u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u></p> <p><u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u></p> <p><u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u></p> <p><u>generating only a portion of said video image based</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and</p>

<u>on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u>	cause said tuner to tune said receiver to receive information of said selected portion.
--	---

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 38
143. A method of outputting a video presentation at a receiver station including: receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal; passing said received video image to an output device for delivery to a user; detecting said at least one first discrete signal; passing information contained in said at least one first discrete signal to a processor in response to said step of detecting; <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u>	38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of: inputting to said controller identification information of at least one specified television or radio program unit; inputting at least part of a programming transmission to said processor; detecting in said part identification data that identifies a specific television or radio program unit; inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 38
152. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is	38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring

<p>adapted to detect the presence of one or more control signals and programmed to process <u>downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station</u>, said method comprising the steps of:</p> <p>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</p> <p>transferring said downloadable processor instructions to a transmitter;</p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p>transferring said one or more control signals to said transmitter; and</p> <p>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</p>	<p>television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>
---	---

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 38
<p>157. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a video image to be transmitted by a remote</p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller</p>

<p>intermediate transmitter station; <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and transmitting said one or more control signals from said origination transmitter before a specific time.</p>	<p>capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of: inputting to said controller identification information of at least one specified television or radio program unit; inputting at least part of a programming transmission to said processor; detecting in said part identification data that identifies a specific television or radio program unit; inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>
---	--

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 38
<p>162. A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of: receiving a video image at a transmitter station; delivering said video image to a transmitter; <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> transferring said at least said first of said plurality of</p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of: inputting to said controller identification information of at least one specified television or radio program unit; inputting at least part of a programming transmission to said processor; detecting in said part identification data that identifies a specific television or radio program unit; inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and</p>

discrete signals to said transmitter; and transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.	cause said tuner to tune said receiver to receive information of said selected portion.
--	--

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 38
<p>167. A method of outputting a video graphic presentation at a receiver station including:</p> <ul style="list-style-type: none"> receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image; passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal of said downloadable code; passing said at least a first discrete signal of said downloadable code to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-</u> 	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <ul style="list-style-type: none"> inputting to said controller identification information of at least one specified television or radio program unit; inputting at least part of a programming transmission to said processor; detecting in said part identification data that identifies a specific television or radio program unit; inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.

<u>screen video graphic image,</u> wherein said method delivers said video graphic presentation.	
---	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 38
<p>171. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is programmed to process said at least one processor instruction, <u>wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image,</u> said method comprising the steps of:</p> <p>receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;</p> <p>transferring said at least one discrete signal to a transmitter;</p> <p><u>receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>

<p><u>screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;</u> transferring said one or more control signals to said transmitter; and transmitting a transmission comprising said at least one discrete signal and said one or more control signals, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 38
<p>175. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</p> <p>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>

<p><u>second completed full-screen video graphic image contains at least one graphic image;</u> <u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u> transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time, wherein said method delivers said video graphic presentation.</p>	
---	--

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 38
<p>177. A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</p> <p>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</p> <p>delivering said received first completed full-screen video graphic image to a transmitter;</p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of:</p> <p>inputting to said controller identification information of at least one specified television or radio program unit;</p> <p>inputting at least part of a programming transmission to said processor;</p> <p>detecting in said part identification data that identifies a specific television or radio program unit;</p> <p>inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and</p> <p>enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>

<p><u>video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u> transferring said one or more instruct signals to said transmitter; and transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station, wherein said method delivers said video graphic presentation.</p>	
--	--

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 38
<p>179. A method of outputting a video graphic presentation at a receiver station including: receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image; passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen; displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen; detecting said at least a first discrete signal; passing said at least a first discrete signal to at least one processor; <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video</u></p>	<p>38. A method for receiving selected television or radio programming in a system that includes a receiver for receiving a television or radio transmission or frequency, a means for transferring television or radio programming from said receiver to a television or radio programming output or storage, a processor capable of receiving and processing at least part of a programming transmission, and a controller capable of receiving information from said processor and of controlling said tuner on the basis of at least some of said information, said method comprising the steps of: inputting to said controller identification information of at least one specified television or radio program unit; inputting at least part of a programming transmission to said processor; detecting in said part identification data that identifies a specific television or radio program unit; inputting information of said identification data to said controller together with information that identifies a specific transmission or frequency; and enabling said controller to select at least a portion of said specific television or radio program unit and cause said tuner to tune said receiver to receive information of said selected portion.</p>

<u>graphic image; and</u> <u>displaying said second completed full-screen video</u> <u>graphic image at said video monitor, said displayed</u> <u>second completed full-screen video graphic image</u> <u>filling the entire surface area of said viewing screen</u> <u>and containing said passed only said portion of said</u> <u>second completed full-screen video graphic image</u> <u>and only a portion of said first completed full-screen</u> <u>video graphic image,</u> wherein said method delivers said video graphic presentation.	
--	--

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations in an operating environment of a receiver station only.

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 39
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>39. A television subscriber station comprising:</p> <p>a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p> <p>a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder;</p> <p>a tuner operatively connected to said means for transferring for selecting a specific television channel; and</p> <p>a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 39
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and output said second video image, said downloadable</u></p>	<p>39. A television subscriber station comprising:</p> <p>a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p> <p>a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder;</p> <p>a tuner operatively connected to said means for transferring for selecting a specific television channel; and</p> <p>a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

<p><u>processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 39
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 39
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>39. A television subscriber station comprising:</p> <p>a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p> <p>a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder;</p> <p>a tuner operatively connected to said means for transferring for selecting a specific television channel; and</p> <p>a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 39
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>39. A television subscriber station comprising:</p> <p>a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p> <p>a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>
--	---

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 39
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 39
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 39
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>39. A television subscriber station comprising:</p> <p style="padding-left: 20px;">a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p> <p style="padding-left: 20px;">a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder;</p> <p style="padding-left: 20px;">a tuner operatively connected to said means for transferring for selecting a specific television channel; and</p> <p style="padding-left: 20px;">a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 39
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 39
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 39
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

<p><u>instructions to a transmitter;</u></p> <p><u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u></p> <p><u>transferring said one or more control signals to said transmitter; and</u></p> <p><u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 39
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u></p> <p><u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u></p> <p><u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>39. A television subscriber station comprising:</p> <p>a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p> <p>a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder;</p> <p>a tuner operatively connected to said means for transferring for selecting a specific television channel; and</p> <p>a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 39
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 39
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>
--	---

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 39
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

selected channel to a television display device or a video recorder;

a tuner operatively connected to said means for transferring for selecting a specific television channel; and

a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 39
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p style="padding-left: 2em;"><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p style="padding-left: 2em;"><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p style="padding-left: 2em;"><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p style="padding-left: 2em;"><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p style="padding-left: 2em;"><u>wherein said method delivers said video graphic presentation.</u></p>	<p>39. A television subscriber station comprising:</p> <p style="padding-left: 2em;">a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p> <p style="padding-left: 2em;">a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder;</p> <p style="padding-left: 2em;">a tuner operatively connected to said means for transferring for selecting a specific television channel; and</p> <p style="padding-left: 2em;">a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 39
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>39. A television subscriber station comprising:</p> <p>a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station;</p> <p>a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder;</p> <p>a tuner operatively connected to said means for transferring for selecting a specific television channel; and</p> <p>a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 39
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>39. A television subscriber station comprising: a processor operatively connected to said subscriber station for collecting statistical information on programming availability, use and usage at said station; a means for receiving a multichannel television transmission and transferring information of a selected channel to a television display device or a video recorder; a tuner operatively connected to said means for transferring for selecting a specific television channel; and a controller operatively connected to said processor and said tuner for obtaining from said processor information associated with said statistical data and for causing said means for receiving to receive a selected channel on the basis of said information.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 40
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source; and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>40. A television subscriber station comprising:</p> <p>a storage device for receiving and storing at least some data associated with a television program presentation;</p> <p>a television receiver for receiving programming associated with said program presentation;</p> <p>a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation;</p> <p>a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content;</p> <p>a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and</p> <p>an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 40
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and</u></p>	<p>40. A television subscriber station comprising:</p> <p>a storage device for receiving and storing at least some data associated with a television program presentation;</p> <p>a television receiver for receiving programming associated with said program presentation;</p> <p>a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation;</p> <p>a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content;</p> <p>a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and</p> <p>an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

<p><u>output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 40
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 40
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u></p> <p><u>receiving video at a transmitter station;</u></p> <p><u>delivering said video to a transmitter;</u></p> <p><u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u></p> <p><u>transferring said first discrete signal to said transmitter; and</u></p> <p><u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>40. A television subscriber station comprising:</p> <p>a storage device for receiving and storing at least some data associated with a television program presentation;</p> <p>a television receiver for receiving programming associated with said program presentation;</p> <p>a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation;</p> <p>a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content;</p> <p>a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and</p> <p>an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 40
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u></p> <p><u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>40. A television subscriber station comprising:</p> <p>a storage device for receiving and storing at least some data associated with a television program presentation;</p> <p>a television receiver for receiving programming associated with said program presentation;</p> <p>a television display device operatively connected to said television receiver and said storage device for</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>
--	--

Claim 93 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 93 over the patented claim's recitations of elements of an apparatus..

Application Claim 110	U.S. Pat. No. 5,335,277, Claim 40
<p>110. <u>A method of outputting a video presentation</u> <u>at at least one of a plurality of receiver stations each of</u> <u>which includes a receiver, a signal detector, a</u> <u>processor, an output device, each of said plurality of</u> <u>receiver stations being adapted to detect the presence</u> <u>of at least one control signal and programmed to</u> <u>process at least one processor instruction, said method</u> <u>comprising the steps of:</u> <u>receiving at at least one transmitter station at least a</u> <u>first discrete signal containing information, wherein</u> <u>said at least one processor instruction comprises</u> <u>information organized from said information</u> <u>contained in said first discrete signal and information</u> <u>contained in a second discrete signal, said at least one</u> <u>processor instruction is effective at said at least one of</u> <u>said plurality of receiver stations to generate and</u> <u>output only a portion of said video presentation, said</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time</p>

<p><u>at least one processor instruction has at said at least one of said plurality of receiver stations a target processor to process data;</u> <u>transferring said at least said first discrete signal to at least one transmitter;</u> <u>receiving said at least one control signal at said at least one transmitter station, wherein said at least one control signal is operative at said at least one of said plurality of receiver stations to organize said information in said first and second discrete signals into said at least one processor instruction; and</u> <u>transferring said at least one control signal to said at least one transmitter, and transmitting at least one information transmission containing said at least said first discrete signal and said at least one control signal.</u></p>	<p>in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>
--	--

Claim 110 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 110 over the patented claim's recitations of elements of an apparatus..

Application Claim 116	U.S. Pat. No. 5,335,277, Claim 40
<p>116. <u>A method of delivering a video presentation at one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said one receiver station displays video received at said one receiver station from a remote intermediate transmitter station and is adapted to display a locally generated image in conjunction with said video in response to at least one processor instruction, said method comprising the steps of:</u> <u>receiving a first discrete signal at an origination transmitter station and delivering said first discrete signal to at least one origination transmitter, wherein said at least one processor instruction is comprised of information contained in said first discrete signal and information contained in a second discrete signal, and wherein one of said one receiver station and said remote transmitter station is adapted to organize said information contained said first discrete signal with said information contained in said second discrete signal;</u> <u>receiving at least one control signal which at said remote transmitter station operates to control the communication of one of said first discrete signal and said at least one processor instruction;</u> <u>transferring said at least one control signal to said at</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

<u>least one origination transmitter before a specific time;</u> <u>and</u> <u>transmitting from said at least origination</u> <u>transmitter said first discrete signal and said at least</u> <u>one control signal.</u>	
---	--

Claim 116 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 116 over the patented claim's recitations of elements of an apparatus..

Application Claim 123	U.S. Pat. No. 5,335,277, Claim 40
<p>123. <u>A method of delivering a video presentation at at least one of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, an output device, and with each of said plurality of receiver stations being adapted to detect the presence of at least one signal, wherein said video presentation includes a first image which is received at one of said plurality of receiver stations from a first remote transmitter station, and wherein one of a code and an identifier is operative at a receiver station of said plurality of receiver stations to designate one of a second image and a device, said method comprising the steps of:</u></p> <p style="padding-left: 20px;"><u>receiving at at least one of said first remote transmitter station and a second remote transmitter station at least one instruct signal which is effective at a particular receiver station of said plurality of receiver stations to generate locally and output said second image of said video presentation for delivery in conjunction with said first image;</u></p> <p style="padding-left: 20px;"><u>transferring said at least one instruct signal to at least one transmitter;</u></p> <p style="padding-left: 20px;"><u>receiving at least one first discrete signal and at least one control signal at said at least one of said first remote transmitter station and said second remote transmitter station, said at least one first discrete signal including only partial information of said one of a code and an identifier and said at least one control signal operative to provide said one of a code and an identifier and designate at said at least one of said plurality of receiver stations by organizing said partial information with information contained in a second discrete signal at said at least one of said plurality of receiver stations, wherein said one of a code and an identifier designates said one of said second image and said device at said particular receiver station and is operative to cause said at least one instruct signal to</u></p>	<p>40. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.

<u>be effective at said at least one of said plurality of receiver stations; and</u> <u>transferring said at least one first discrete signal and said control signal to said at least one transmitter, said at least one transmitter station transmitting at least one information transmission containing said instruct signal, said at least one first discrete signal, and said control signal to said plurality of receiver stations.</u>	
--	--

Claim 123 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 123 over the patented claim's recitations of elements of an apparatus..

Application Claim 142	U.S. Pat. No. 5,335,277, Claim 40
<p>142. <u>A method of outputting a video presentation at a receiver station, said video presentation including a video image, said method comprising the steps of:</u> <u>receiving an information transmission at said receiver station, said information transmission containing at least a first discrete signal and at least one control signal;</u> <u>detecting said at least a first discrete signal and said at least one control signal in said information transmission;</u> <u>passing said detected at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on said at least one control signal;</u> <u>passing at least one processor instruction from or within said at least one processor, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>responding to said at least one processor instruction at said receiver station based on said step of passing said at least one processor instruction;</u> <u>generating only a portion of said video image based on said step of responding to said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said video presentation containing said generated only said portion of said video image.</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

Claim 142 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 142 over the patented claim's recitations of elements of an apparatus..

Application Claim 143	U.S. Pat. No. 5,335,277, Claim 40
<p>143. <u>A method of outputting a video presentation at a receiver station including:</u> <u>receiving a transmission from a remote station, said transmission containing a video image and at least one first discrete signal;</u> <u>passing said received video image to an output device for delivery to a user;</u> <u>detecting said at least one first discrete signal;</u> <u>passing information contained in said at least one first discrete signal to a processor in response to said step of detecting;</u> <u>organizing said information contained in said at least one first discrete signal at said receiver station with information contained in at least one second discrete signal;</u> <u>responding, at said processor, to processor instructions comprising said organized information, based on said step of organizing;</u> <u>generating a signal based on said processor instructions; and</u> <u>outputting at least a portion of said video presentation based on said generated signal.</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

Claim 143 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 143 over the patented claim's recitations of elements of an apparatus..

Application Claim 152	U.S. Pat. No. 5,335,277, Claim 40
<p>152. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of one or more control signals and programmed to process downloadable processor instructions that, at said at least one receiver station, are effective to generate and output a local image of said video presentation and have a target processor to process data, said video presentation comprised of said local image of said video presentation and a video image which is received at said at least one receiver station from a first remote transmitter station, said method comprising the steps of:</u> <u>receiving at one of said first remote transmitter station and a second remote transmitter station said downloadable processor instructions;</u> <u>transferring said downloadable processor</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for</p>

<p><u>instructions to a transmitter;</u> <u>receiving said one or more control signals at said one of said first remote transmitter station and a second remote transmitter station, wherein said one or more control signals are operative at said at least one receiver station to direct said video image to said output device, designate a processor to execute said downloadable processor instructions, or designate a user input to be processed based on said downloadable processor instructions, and wherein said one or more control signals enable said at least one receiver station to display said local image of said video presentation in conjunction with said video image;</u> <u>transferring said one or more control signals to said transmitter; and</u> <u>transmitting a transmission comprising said downloadable processor instructions and said one or more control signals.</u></p>	<p>inputting an instruct-to-coordinate signal.</p>
---	--

Claim 152 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 152 over the patented claim's recitations of elements of an apparatus..

Application Claim 157	U.S. Pat. No. 5,335,277, Claim 40
<p>157. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of signals, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, a video image to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal to an origination transmitter, wherein said signal contains said video image and includes an instruct signal which is effective at said at least one receiver station to generate and output a local image of said video presentation, wherein said local image is outputted at said at least one receiver station in conjunction with said video image;</u> <u>receiving, at said origination transmitter station, one or more control signals, wherein said one or more control signals operate at said remote intermediate transmitter station to control the communication of at least one of said video image, and said instruct signal; and</u> <u>transmitting said one or more control signals from said origination transmitter before a specific time.</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

Claim 157 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 157 over the patented claim's recitations of elements of an apparatus..

Application Claim 162	U.S. Pat. No. 5,335,277, Claim 40
<p>162. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, wherein said at least one receiver station is programmed to process code and adapted to detect at least a first of a plurality of discrete signals, said code comprised of information contained in each of said plurality of discrete signals, said method comprising the steps of:</u> <u>receiving a video image at a transmitter station;</u> <u>delivering said video image to a transmitter;</u> <u>receiving said at least said first of said plurality of discrete signals at said transmitter station, wherein said at least said first of said plurality of discrete signals enables said at least one receiver station to process said code by organizing information contained in said at least said first of said plurality of discrete signals with information contained in a second of said plurality of discrete signals and, thereby, to respond to said code, and wherein said code enables said at least one receiver station to generate or identify a local image and output said local image in conjunction with said video image;</u> <u>transferring said at least said first of said plurality of discrete signals to said transmitter; and</u> <u>transmitting said video image and said at least said first of said plurality of discrete signals from said transmitter station to said at least one receiver station.</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

Claim 162 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 162 over the patented claim's recitations of elements of an apparatus..

Application Claim 167	U.S. Pat. No. 5,335,277, Claim 40
<p>167. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal of downloadable code and a first completed full-</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming</p>

<p><u>screen video graphic image, said first completed full-screen video graphic image containing at least one graphic image;</u> <u>passing said received first completed full-screen video graphic image to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying said first completed full-screen video graphic image at said video monitor, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal of said downloadable code;</u> <u>passing said at least a first discrete signal of said downloadable code to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying, at said video monitor, said second completed full-screen video graphic image, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only a portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>
--	--

Claim 167 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 167 over the patented claim's recitations of elements of an apparatus..

Application Claim 171	U.S. Pat. No. 5,335,277, Claim 40
<p>171. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, is adapted to detect the presence of one or more control signals, and is</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to</p>

programmed to process said at least one processor instruction, wherein said at least one processor instruction instructs said at least one receiver station to pass only a portion of a second completed full-screen video graphic image to said video monitor, wherein said second completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor and contains said only a portion of said second completed full-screen video graphic image and only a portion of a first completed full-screen video graphic image, wherein said first completed full-screen video graphic image fills the entire surface area of said viewing screen when displayed at said video monitor, and wherein said second completed full-screen video graphic image contains at least one graphic image, said method comprising the steps of:

receiving at a transmitter station at least one discrete signal that contains only partial information of said at least one processor instruction and serves as a basis for providing said at least one processor instruction at said at least one receiver station;

transferring said at least one discrete signal to a transmitter;

receiving said one or more control signals at said transmitter station, wherein said one or more control signals are operative at said at least one receiver station to provide said at least one processor instruction by causing said at least one receiver station to organize said partial information with information contained in a second discrete signal, said at least one processor instruction directing, to said video monitor, said only a portion of said second completed full-screen video graphic image, said viewing screen displaying said only a portion of said second completed full-screen video graphic image in conjunction with said only a portion of said first completed full-screen video graphic image;

transferring said one or more control signals to said transmitter; and

transmitting a transmission comprising said at least one discrete signal and said one or more control signals,

wherein said method delivers said video graphic presentation.

said television receiver and said storage device for displaying said television program presentation;

a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content;

a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and

an input operatively connected to said controller for inputting an instruct-to-coordinate signal.

Claim 171 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 171 over the patented claim's recitations of elements of an apparatus..

Application Claim 175	U.S. Pat. No. 5,335,277, Claim 40
<p>175. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations, each receiver station of said plurality of receiver stations being adapted to detect the presence of signals and including a receiver, a signal detector, a processor, and a video monitor, said video monitor having a viewing screen, said method comprising the steps of:</u></p> <p><u>receiving, at an origination transmitter station, a first completed full-screen video graphic image that fills the entire surface area of said viewing screen when displayed at said video monitor, said first completed full-screen video graphic image to be transmitted by a remote intermediate transmitter station and displayed at said video monitor;</u></p> <p><u>delivering a signal to an origination transmitter, said signal containing said first completed full-screen video graphic image and at least one discrete signal that contains only a part of at least one processor instruction that instructs said at least one receiver station to generate and output only a portion of a second completed full-screen video graphic image, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of a second completed full-screen video graphic image in conjunction with only a portion of said first completed full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>receiving, at said origination transmitter station, one or more control signals, said one or more control signals operate at the remote intermediate transmitter station to control the communication of at least one of said first completed full-screen video graphic image and said at least one discrete signal, said at least one processor instruction, and said second completed full-screen video graphic image; and</u></p> <p><u>transmitting a transmission that contains said at least one discrete signal, said first completed full-screen video graphic image and said one or more control signals from said origination transmitter before a specific time,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>40. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.

Claim 175 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 175 over the patented claim's recitations of elements of an apparatus..

Application Claim 177	U.S. Pat. No. 5,335,277, Claim 40
<p>177. <u>A method of delivering a video graphic presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor to execute at least one processor instruction, and a video monitor that has a viewing screen, and is adapted to detect the presence of signals, said method comprising the steps of:</u></p> <p><u>receiving a first completed full-screen video graphic image at a transmitter station, said first completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor;</u></p> <p><u>delivering said received first completed full-screen video graphic image to a transmitter;</u></p> <p><u>receiving one or more instruct signals at said transmitter station, said one or more instruct signals at said at least one receiver station designating at least one processor instruction that is operative at said at least one receiver station to generate or identify locally and pass only a portion of a second completed full-screen video graphic image to said video monitor, said second completed full-screen video graphic image filling the entire surface area of said viewing screen when displayed at said video monitor and containing said only a portion of said second complete full-screen video graphic image and only a portion of said first complete full-screen video graphic image, wherein at least one of said first completed full-screen video graphic image and said second completed full-screen video graphic image contains at least one graphic image;</u></p> <p><u>transferring said one or more instruct signals to said transmitter; and</u></p> <p><u>transmitting said first completed full-screen video graphic image and said one or more instruct signals from said transmitter station to said at least one receiver station,</u></p> <p><u>wherein said method delivers said video graphic presentation.</u></p>	<p>40. A television subscriber station comprising:</p> <ul style="list-style-type: none"> a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.

Claim 177 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 177 over the patented claim's recitations of elements of an apparatus..

Application Claim 179	U.S. Pat. No. 5,335,277, Claim 40
<p>179. <u>A method of outputting a video graphic presentation at a receiver station including:</u> <u>receiving, from a remote transmitter station, a transmission that contains at least a first discrete signal and a series of video images that each contain at least one graphic image;</u> <u>passing said received series of video images to a video monitor for delivery to a user, said video monitor having a viewing screen;</u> <u>displaying, at said video monitor, a first completed full-screen video graphic image based on said series of video images, said displayed first completed full-screen video graphic image filling the entire surface area of said viewing screen;</u> <u>detecting said at least a first discrete signal;</u> <u>passing said at least a first discrete signal to at least one processor;</u> <u>organizing information contained in said at least a first discrete signal at said receiver station with information contained in a second discrete signal based on at least one control signal;</u> <u>responding to at least one processor instruction at said receiver station, said at least one processor instruction comprising said organized information from said step of organizing;</u> <u>passing, to said video monitor based on said step of responding to at least one processor instruction, only a portion of a second completed full-screen video graphic image; and</u> <u>displaying said second completed full-screen video graphic image at said video monitor, said displayed second completed full-screen video graphic image filling the entire surface area of said viewing screen and containing said passed only said portion of said second completed full-screen video graphic image and only a portion of said first completed full-screen video graphic image,</u> <u>wherein said method delivers said video graphic presentation.</u></p>	<p>40. A television subscriber station comprising: a storage device for receiving and storing at least some data associated with a television program presentation; a television receiver for receiving programming associated with said program presentation; a television display device operatively connected to said television receiver and said storage device for displaying said television program presentation; a decoder operatively connected to a mass medium receiver for detecting and transferring to said storage device at least one datum that identifies specific programming content; a controller operatively connected to said storage device and said display device for causing said storage device to transmit at least some programming content associated with said datum at a specific time in response to an instruct-to-coordinate signal; and an input operatively connected to said controller for inputting an instruct-to-coordinate signal.</p>

Claim 179 recites methods for accomplishing certain steps in the operating environment of a receiver station. This differentiates claim 179 over the patented claim's recitations of elements of an apparatus..

Application Claim 56	U.S. Pat. No. 5,335,277, Claim 41
<p>56. <u>A method for receiving and processing data for use with an interactive video apparatus, said interactive video apparatus having a video output device for displaying a video presentation comprising a locally generated image and an image received from a remote video source, said method comprising the steps of:</u></p> <p><u>originating at said interactive video apparatus at least a first request in order to enable content to be displayed in said video presentation;</u></p> <p><u>communicating one of said at least said first request and a second request to a remote data source;</u></p> <p><u>receiving from said remote data source said data to serve as a basis for displaying said video presentation;</u></p> <p><u>processing said data at said interactive video apparatus in order to present said locally generated image with said image from said remote video source;</u></p> <p><u>and</u></p> <p><u>displaying said locally generated image at said video output device in conjunction with said image from said remote video source.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising:</p> <p>a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 56 recites methods for accomplishing certain steps in the operating environment of a receiver station, i.e., an interactive video apparatus. This differentiates claim 56 over the patented claim's recitations of elements of an apparatus..

Application Claim 75	U.S. Pat. No. 5,335,277, Claim 41
<p>75. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and each of which is adapted to detect the presence of at least one control signal and programmed to process downloadable processor instructions, said video presentation including a first video image and a second video image, said first video image received at said at least one receiver station from a first remote transmitter station, said second video image containing at least one datum that at least one of completes and supplements said first video image and displayed in conjunction with said first video image, said method comprising the steps of:</u></p> <p><u>receiving at one of said first transmitter station and a second transmitter station said downloadable processor instructions, wherein said downloadable processor instructions are capable of causing said at least one receiver station to generate locally and</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising:</p> <p>a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

<p><u>output said second video image, said downloadable processor instructions having at said at least one receiver station a target processor to process data;</u> <u>transferring said downloadable processor instructions to a transmitter;</u> <u>receiving said at least one control signal at said one of said first and second transmitter station, wherein said at least one control signal is effective at said at least one receiver station to control execution of at least one of said downloadable processor instructions and deliver at least said second video image of said video presentation;</u> <u>transferring said at least one control signal to said transmitter; and</u> <u>transmitting an information transmission comprising said downloadable processor instructions and said at least one control signal.</u></p>	
--	--

Claim 75 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 75 over the patented claim's recitations of elements of an apparatus..

Application Claim 80	U.S. Pat. No. 5,335,277, Claim 41
<p>80. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, said method comprising the steps of:</u> <u>receiving, at an origination transmitter station, video to be transmitted by a remote intermediate transmitter station;</u> <u>delivering a signal containing said video to an origination transmitter, said signal containing said video also containing an instruct signal which is operative at said at least one receiver station to instruct said at least one receiver station to at least one of generate and output a local portion of a video presentation and cause said locally generated portion of said video presentation to be displayed in conjunction with said video;</u> <u>receiving, at said origination transmitter station, at least one control signal that, at the remote intermediate transmitter station, controls the communication of at least one of said video and said instruct signal; and</u> <u>transmitting said at least one control signal from said origination transmitter before a specific time.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 80 recites methods for accomplishing certain steps in the operating environment of an origination transmitter station, a remote intermediate transmitter station and a receiver station. This differentiates claim 80 over the patented claim's recitations of elements of an apparatus..

Application Claim 84	U.S. Pat. No. 5,335,277, Claim 41
<p>84. <u>A method of delivering a video presentation at at least one receiver station of a plurality of receiver stations each of which includes a receiver, a signal detector, a processor, and an output device, and is adapted to detect the presence of at least one signal, wherein at least one processor instruction comprises information content of separate ones of a plurality of discrete signals and said at least one receiver station is capable of providing said at least one processor instruction, said method comprising the steps of:</u> <u>receiving video at a transmitter station;</u> <u>delivering said video to a transmitter;</u> <u>receiving a first discrete signal of said plurality of discrete signals at said transmitter station, wherein said first discrete signal is operative to provide said at least one processor instruction at said at least one receiver station by enabling said at least one receiver station to organize information contained in said first discrete signal with information contained in a second of said plurality of discrete signals, and said at least one processor instruction instructs said at least one receiver station to deliver a locally generated image for display in conjunction with said video;</u> <u>transferring said first discrete signal to said transmitter; and</u> <u>transmitting said video and said first discrete signal to said at least one receiver station.</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising: a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>

Claim 84 recites methods for accomplishing certain steps in the operating environment of a remote transmitter station and a receiver station. This differentiates claim 84 over the patented claim's recitations of elements of an apparatus..

Application Claim 93	U.S. Pat. No. 5,335,277, Claim 41
<p>93. <u>A method of outputting a video presentation at a receiver station, said video presentation comprising a sequence of outputs and including, as a first of said sequence of outputs, a video image, said method comprising the steps of:</u> <u>receiving at least one information transmission at said receiver station, said at least one information transmission containing at least one first discrete</u></p>	<p>41. A system for processing a television program transmission in which a plurality of types of signals including identification signals or instruct-to-decrypt signals are transmitted, said types being transmitted in different patterns and at least one of said types being transmitted in varying locations or in a varying pattern of timing in said program transmission, said system comprising:</p>

<p><u>signal and at least one control signal;</u> <u>detecting said at least one first discrete signal and</u> <u>said at least one control signal in said at least one</u> <u>information transmission;</u> <u>passing said detected at least one first discrete signal</u> <u>and said detected at least one control signal to at least</u> <u>one processor;</u> <u>organizing information contained in said at least</u> <u>one first discrete signal at said receiver station with</u> <u>information contained in a second discrete signal</u> <u>based on said at least one control signal;</u> <u>passing at least one processor instruction from or</u> <u>within said at least one processor, said at least one</u> <u>processor instruction comprising said organized</u> <u>information from said step of organizing;</u> <u>responding to said at least one processor instruction</u> <u>at said receiver station based on said step of passing</u> <u>said at least one processor instruction;</u> <u>generating an image to replace only a portion of</u> <u>said video image by processing at least one stored</u> <u>subscriber datum based on said step of responding to</u> <u>said at least one processor instruction; and</u> <u>outputting said video presentation to a user, said</u> <u>video presentation containing, firstly, said video</u> <u>image and, secondly, said generated image to replace</u> <u>said only said portion of said video image.</u></p>	<p>a processor for identifying and transferring to a computer an instruct-to-generate signal that causes said computer to generate a portion of the video information content of a television program to be displayed at a television display device.</p>
